Indeed, only one question remains unanswered. Does the imprint "Oxford University Press" on the title page mean what it says or (into Basque through Minoan) something different? JOHN L. MYRES

## Short Reviews

*Studies in the Literature of Natural Science* By Julian M. Drachman Pp xi+487+6 plates (New York The Macmillan Co., 1931) 17s net

As science becomes more and more popular, the man of science can no longer isolate himself in the laboratory, he must communicate his attainments to the general public in books which can be read without spending a lifetime in the mere learning of an alphabet. If it could be shown that the writers of scientific classics produced what in some cases were works of literary art, that might be a more convincing argument still. Such is the task which the author of this interesting book sets himself to do. He confines his research to the literature of natural science in the nineteenth century, which is dominated by men of genius like Darwin, Lyell, Owen, Huxley, and Tyndall, pointing out in each case how art and science are happily interconnected. The general conclusion of this historical investigation is that the writer of books on scientific subjects can vastly increase the number of his readers and the efficiency of his presentation by means of increased attention to the literary art.

Besides a number of interesting quotations from the sources, and the novel commentary presented by the author of several classical scientific works, there are two points in this book which should be mentioned. One is the new 'cyclical' classification of the sciences, which are divided into four groups—mental, human, natural, physical—each of which is further divided into sub-groups. The arrangement illustrates in a striking manner the mutual interdependence of the sciences. The other point is a questionnaire on the literature of science which was answered by various scientific workers and writers, and is intended to show that there is no essential contradiction between literature and science. Huxley's "Essays" have had more votes than any other as a "particularly fine book of popular science." T G

*A Manual of the Dragonflies of China a Monographic Study of the Chinese Odonata* By Prof. James G. Needham (Zoologia Sinica, Series A. Invertebrates of China, Vol. 11, Fascicle 1) Pp ii + 344 + 11 + 20 plates (Peiping The Fan Memorial Institute of Biology, 1930) 5 dollars, 20s

THIS bulky memoir is based upon researches that were supported by a grant from the Heckscher Foundation of Cornell University, and it forms a notable contribution to a knowledge of the little explored insect fauna of China. The material which rendered the work possible was obtained from many sources and includes that collected by Dr. Needham during a year's residence in China. Altogether 266 species of dragonflies are described, of which 58 are regarded as being new to science. They are included in 89 genera, of which the single genus *Simolestes* is new. The memoir is very fully illustrated by 20 plates which portray structural

details of both adults and of the few nymphs that have yet been discovered. We congratulate the author, and those responsible for its publication, upon the production of a work that will be welcomed by students of the Odonata throughout the world.

*Thought Transference (or What?) in Birds* By Edmund Selous Pp xi+255 (London Constable and Co., Ltd., 1931) 7s 6d net

MR. SELOUS holds a high place as an observer of bird behaviour, and in the present small volume he gives much admirable description in support of his view that the concerted actions of flocks can be explained only by postulating some kind of 'thought transference' between the members. The apparently simultaneous rising of a flock of rooks without obvious extraneous stimulus, the unanimity with which a party of dunlins wheel in their dashing flight, the sudden hush that stills the screaming of a colony of terns—these and many other examples of community behaviour the author observes over and over again with minute care.

The crux lies, of course, in the interpretation, and the reader may doubt whether the human eye is not deceived by an appearance of simultaneity that is in fact an extreme rapidity of imitative action. The author, indeed, seems to give part of his case away when he describes instances in which the movement could be seen spreading through the flock. Even so, there are difficulties, for why are some movements of individuals instantly conformed with by all the rest, while other movements—as the author points out—are ignored by the majority? The phenomenon is, at the least, a remarkable one, but Mr. Selous admits that his explanation would itself require to be explained. The author's method of presenting his matter in the raw, that is, wholly in the form of extracts from his diary embellished with footnotes, will probably appeal to some readers, but it will repel those who prefer a more orderly marshalling of evidence and argument.

*The British Journal Photographic Almanac and Photographer's Daily Companion with which is incorporated 'The Year Book of Photography and Amateurs' Guide' and 'The Photographic Annual', 1932* Edited by George E. Brown Pp 684 + 64 plates (London Henry Greenwood and Co., Ltd., 1932) Paper, 2s net, cloth, 3s net

THIS well-known handbook for photographers needs no introduction to readers of NATURE: it has been published annually for more than sixty years. This year there are five articles by well-known writers on photography. The latest advances in photography and photographic apparatus are discussed in a space of one hundred and sixteen pages. A further eighty-four pages gives a great mass of formulæ and other technical information. Not least in importance are the advertisements, which are very numerous and sufficiently descriptive to be of great use in a handbook of photography. The examples of pictorial photography cover a wide range of subjects and are well produced in photogravure. S O R

## Photo-Elasticity

LONG ago it was remarked by Brewster that a transparent elastic solid such as glass ceases to be optically isotropic when it is bent or otherwise strained by external forces. It then shows chromatic effects in the polariscope, which vanish if the state of strain be relieved. That was the beginning of photo-elasticity, a science which, many years later, has become developed into a powerful means of investigating complex conditions of stress for the information of the engineer. It can readily be applied in cases which are too complicated for mathematical analysis, and even in less complex conditions photo-elastic experiments are often highly useful, providing short-cuts to the required results, or confirming the analysis of the mathematician. Whether the distribution of stress is simple or otherwise, the photo-elastic method makes the mode of distribution strikingly apparent. The polariscope is an incomparable showman, as entertaining as it is instructive. It appeals alike to the mathematical and the non-mathematical mind. The distribution of stress exhibited by the transparent solid applies to an engineering material such as steel, provided the elastic limit is not passed.

Lately, I saw in Prof. Coker's laboratory a transparent model of a locomotive driving-wheel revolving in contact with a loaded roller which pressed on the rim as the rail presses on the real wheel, the whole working in circularly polarised light and throwing its image on a screen. The chromatic effects, as each part of the rim and each spoke in turn took up its duty and then passed it on, made a brilliant spectacle—as fascinating a 'movie' as any engineer could wish to see, all the more as the spectator could control the speed or introduce a pause at any stage.

In modern developments of the subject the favourite medium for the study of stress is not glass but some form of celluloid. Xylonite, which engineers know as a material of which set-squares are often made, answers well. It is inexpensive, and is easily procured in transparent plates which are sufficiently uniform in thickness and quality, are free from internal stress, and come near enough to the ideal of perfect elasticity. It is not brittle, and is easily cut into strips or rings or flat pieces of any form, so that it may serve as a replica in miniature of the engineering article the behaviour of which under stress is to be studied—such, for example, as a plate weakened by rivet-holes. Readers of NATURE who are unacquainted with the subject may like to be told briefly what is the process by which the polariscope is made to reveal the condition of stress in such a specimen.

Imagine, then, an optical bench with a source of light such as a pointlight lamp at one end and a projection screen at the other. The bench carries a pair of crossed Nicol prisms, between which the specimen is placed—a flat strip or plate of xylonite a quarter of an inch thick, or less, with its plane at right angles to the rays—so that light polarised by the first Nicol passes through the specimen in the

direction of the thickness. The piece is held in what is virtually a small testing-machine, in order that measured loads—pulls or pushes or both—may be readily applied in its own plane. Each of the Nicols is furnished with a removable quarter-wave plate of mica, allowing either circularly polarised or plane polarised light to be used at pleasure, and the Nicols may be rotated together in order that their crossed axes may be set at any angle to fixed axes in the specimen. The specimen is cut from a uniformly thick plate, so that the polarised light traverses the same thickness at all points of the material under examination.

So long as no load is applied, the material is isotropic, and has consequently no action on the polarised light. In that condition no light passes through, for the second Nicol stops what has come through the first. But let stress be applied, the xylonite then develops a birefringent quality, causing a relative retardation of part of the polarised ray, with the result that colour effects appear on the screen. To take the simplest case, let the piece be a strip under uniform tensile stress in the direction of its length, then the image will have a definite uniform colour depending on the amount of that stress, and as the stress is increased the colour will change through a sequence of tints that correspond to Newton's colour scale for thin plates. Let uniform push be applied instead of pull, and gradually increased, the same sequence of colours is again seen, the colour for push being the same as for an equal intensity of pull. Or, to take another example, let the piece be stressed as a beam under uniform bending moment in its own plane, the image will then show a set of longitudinal colour bands. The neutral axis will appear as a black central band, since there is no stress there, and on either side of it—above and below—there will be a series of parallel colour bands grading into one another, which show how the intensity of longitudinal push or pull increases with the distance from the neutral axis towards one or the other edge.

In each of these examples there is only one principal stress  $P$  at any point, and the colour there directly exhibits the value of  $P$ . But in general, for less simple states of elastic strain in a loaded plate, there will be two principal stresses  $P$  and  $Q$ , at right angles to each other, and it is easy to show that what the colour really tells is the difference  $P - Q$ . At any point where  $Q$  happens to be equal to  $P$  no light gets through the polariscope. There the image has a dark spot; at all other places there is colour. As the magnitude of  $P - Q$  increases from point to point of the plate the tint changes, following the Newton colour sequence, and the image on the screen accordingly exhibits strong colouring in the form of isochromatic curves, each such curve being a locus of points at which the value of  $P - Q$  is constant. Incidentally, therefore, these isochromatic curves exhibit directly the amount of shearing stress at each point, for the shearing stress is everywhere proportional to  $P - Q$ .

The main object of the test, however, is to determine the principal stresses separately, and for that a further experimental analysis is required. We now change from circularly polarised light (which was best for exhibiting the isochromatic curves) to plane polarised light, by removing the quarter-wave plates, and set the crossed nicols at a particular azimuth or direction in the plane of the plate. The image now shows certain dark bands corresponding to places at which the two directions of principal stress are parallel to the axes of the two nicols. A locus of such points is called an isoclinic curve, for at these points the principal stresses have constant inclinations with respect to any arbitrarily chosen co-ordinate axes. Points on the isoclinic are recorded by marking the screen with little parallel crosses, the limbs of which lie in the directions of the principal stresses, these directions being given by the setting of the crossed nicols. Next, the setting is changed by turning the nicols through, say,  $15^\circ$ , and another isoclinic is then observed and is recorded in the same way. Proceeding thus, with progressive turning of the nicols through  $15^\circ$  at a time, we obtain a complete system of isoclinics for the whole plate, from which it is easy, by aid of the marked crosses, to sketch in the double system of lines of principal stress.

These lines give everywhere the directions of  $P$  and  $Q$ , but the magnitudes of  $P$  and  $Q$  have still to be determined. The colour bands, as we have seen, depend on  $P - Q$ , and the value of that quantity may be inferred by matching the colour at any point of the strained specimen with the colour shown by a strip of the same material and thickness strained by a known simple pull. But accurate colour matching is not easy, and a very much better way, due to Coker, is to superpose the auxiliary strained strip so that the polarised light passes in series through it as well as through the main specimen. The auxiliary strip is set so that the direction of pull in it is at right angles to the principal stress  $P$  at the place under examination. Then by adjusting the stress  $P'$  in it until a black spot appears in the image, we know that  $P = Q + P'$ , and hence  $P'$  gives a direct measure of  $P - Q$ .

To find the value of  $P - Q$  is not enough when we want separate values of  $P$  and of  $Q$ , so, following Mesnager, Coker carries out a supplementary observation. By means of a delicate lateral extensometer, which measures the elastic change of thickness of the plate at any point, he infers  $P + Q$  from the observed amount of lateral contraction. Then, combining this information with the results of the optical tests, the whole problem is solved,  $P$  and  $Q$  are each determined, in magnitude and direction at every point. The process is laborious, but the final results are complete and convincing in many cases they can be usefully checked by integrating graphically over a section on which the whole stress is known from the conditions of loading. Often the process may be simplified by starting from a free edge, where one of the principal stresses is necessarily zero.

All this, and much more, is fully discussed by Profs Coker and Filon in their recently issued

treatise,\* along with an account of how the method has been applied to a host of important practical examples. This fine volume, with its 720 large pages of print, its numerous colour plates, and its many hundreds of admirably drawn illustrations, is a monument not only to the ability and industry of the joint authors, but also to the enterprise and technical skill of the producers, the Cambridge University Press. The typographic form is worthy of the matter, and to say that is high praise. The authors here treat with affectionate completeness a subject they have made peculiarly their own. They have spent many years in perfecting it and demonstrating its uses. Much of their original work has been done in close association. Now they present us with the fruits of a happy collaboration in authorship, where the critical insight of the mathematician and the practical flair of the engineer combine to provide a comprehensive, systematic, and extremely lucid treatise. Readers who know both authors may find material in the book for an interesting guessing game, as to which parts, so to speak, are Sullivan's and which are Gilbert's. But the main point is that the whole is a good blend. The authors make an exceedingly strong team, they pull well together and each supplements the many virtues of the other.

After a short introduction, we have several chapters of general theory. The relevant optics are discussed on the basis of Maxwell's electromagnetic waves, and this is followed by a chapter on the theory of elasticity, before the theory of artificial double refraction is attacked, on which the whole process depends. The first half or so of the work will be of general interest to physicists, apart from the solution of special problems of engineering with which the later sections abound. These comprise many detailed applications of the method, to tension and compression test-pieces and pieces under shear, to beams and bridges, to thick cylinders, to plates with holes and notches and cracks, to eye-bolts and fastenings, to rings, chains, hooks, wheels, to the action of cutting tools, and to other examples too numerous for mention here. Some of them are very recent—they include studies undertaken by Coker for a special committee of the Department of Scientific and Industrial Research, which has not yet reported, in critical examination of certain customary types of test. All of them illustrate the wide sweep of the method, its power to illuminate obscure matters, and its great value as a guide in design. To have produced such a work is a professional service for which engineers—contemporary and future—cannot fail to be deeply grateful.

Such a treatise was, in fact, greatly needed. It is a new departure: no book has hitherto been available that covers anything like the same ground. Students of the subject have had to refer to scattered papers or lectures, many of them by Coker and Filon themselves. The book will be welcomed as filling a definite gap in the literature.

\* *A Treatise on Photo-Elasticity*. By Prof. E. G. Coker and Prof. L. N. G. Filon. Pp. xviii + 720 + 14 plates. (Cambridge: At the University Press, 1931.) 50s. net.

of scientific engineering. Engineers know that the methods of photo-elasticity—methods of experiment with which they are still for the most part unfamiliar—have already become important auxiliaries in design. Such a treatise will, I believe, be no less attractive to the physicist, to whom it will appeal in the rare moments which find him willing to turn aside from the atom and the photon to revise, and perhaps enlarge, his ideas of what happens to the 'classical' Maxwellian waves when they traverse solid aggregates. If he discovers how to harmonise the two modes of thought, so much the better.

There is, paradoxically enough, one defect. The book is so big, so full, so thorough, that it must fail of one important purpose: it is not a textbook for the ordinary student of engineering. He needs something much more brief, direct, and simple—something that will show him the optical bench and tell him plainly how to use it. So many elementary accounts have already appeared in lectures and addresses to learned societies that the authors must be tired of that kind of exposition, but it still needs to be embodied in a handbook that will be a really handy book. Such a task is well worth doing. This excellent voluminous

treatise will always be there for more advanced study and as an encyclopædia of reference the small book, which has yet to be written, would introduce readers to it and would spread knowledge, in a way the treatise cannot be expected to do, of a subject which should be taught in every engineering laboratory, and should become, at least in its elements, part of the mental equipment of every educated engineer.

To me the book brings a personal pleasure, for it happens that both Coker and Filon were at one time my pupils. It was in the engineering laboratory at Cambridge, more than thirty years ago, that Filon carried out his earliest photo-elastic research on a loaded beam of glass. For that, however, I can claim no credit, not even the credit of suggestion. His experiments were initiated and pursued in a fine spirit of independence, a virtue only too rare among research students. Nor had I any hand in the subsequent efforts, successful and long sustained, to which this book bears witness. But even so, it gives an old teacher some satisfaction to see original work of high quality proceed from those whose early notions he may have had some small share in shaping, and to sit, as I now do, a learner at their feet.

J. A. EWING

### Albertus Magnus

#### HIS SCIENTIFIC VIEWS

"EVERYTHING there was to be known, he knew." Thus is the genius of Albert the Great characterised by the Pope in the remarkable Bull "In Thesaurus Sapientiæ" declaring the blessed Bishop of Regensburg a saint and a doctor of the Church. In this "Decretal Letter", dated Dec. 16, 1931, but published on Jan. 14, 1932, Pope Pius XI points out that Albert the Great (1206–1280) was not only a lover of God, a pastor of souls, and a master of the sacred sciences, but also a pioneer in secular knowledge. He wrote about astronomy, physics, mechanics, chemistry, mineralogy, anthropology, zoology, botany, architecture, and the applied arts, and the modern edition of his writings makes thirty-eight thick quarto volumes (ed. Jammy O. P. repr. Vivès, Paris, 1890 sq.). Indeed, Albert the Great broke the chains that kept natural science in the hands of unbelievers, and vindicated it against the more timid pious persons of his time who were afraid of it for fear of its abuse. For, says the Pope, "no real theologian is afraid of any damage from the operations of nature or of natural reason rightly investigated, for these very things bear upon them the light of the Creator himself."

We do not propose here to give any account of the edifying and active life of St. Albert the Great, or to report on the various causes which led to his canonisation by the Church. Nor do we intend to give an outline of the theological and philosophical views of a master mind who is now honoured as one of the twenty-eight doctors of the Church, together with Gregory, Basil, Ambrose, Augustine,

Jerome, Thomas Aquinas, Anselm, Bernard, Bede, Ephraem, John of the Cross, and Bellarmine. We shall endeavour, however, to give a short sketch of the scientific views of Albert the Great, which are of the greatest interest for the history of science, especially as they represent the state of scientific knowledge in the Middle Ages.

Though Albert seems to be less original and forceful as a scientific thinker than his contemporary Roger Bacon, yet he was far more influential on the age in which he lived. The peculiarity of his encyclopædic teaching was that it was based entirely on the writings of Aristotle. This was remarkable because the Aristotelian principles were resisted by the Church at the time, the provincial council at Siena in 1210 going so far as to forbid the use of Aristotle's books on natural philosophy. But though no professor was permitted to lecture on them, and in spite of the fact that in 1215 the "Physics" and the "Metaphysics" were banned by the statutes of the University of Paris, Albert the Great was actively promoting the new philosophy, probably with the connivance of the Church authorities, who allowed a responsible theologian to sift the true from the false while they acted as the stern guardians of orthodoxy. He soon joined hands with his pupil Thomas Aquinas, who, if he surpassed his master in the theological and philosophical interpretations of the Stagyrte's system, does not, however, compare favourably with Albert in his scientific studies.

The astronomical beliefs of Albert, though partly

inspired by Aristotle, differ widely on many important points from the views of the Stagyrte. Albert taught that the heavens move from east to west carrying along with them their particular stars which move from west to east, "something like the motion of an ant on a wheel rotating in a contrary direction." The whole world is like a huge machine moved by God according to secret principles which the human intellect, however, can partly discover. Each star, in turn, is moved by a pure intellect, each having its own heavens with its particular motion, so that the circles of the stars are not concentric, as Aristotle on the authority of Eudoxus taught, but eccentric as in Ptolemy's system. Yet the earth is at the centre of the world, the heavens of the Moon, Venus, Mercury, the Sun, Mars, Jupiter, Saturn, the fixed stars, the aqueous, the crystalline and the empyreal heavens, coming in succession, the last-named being the dwelling-place of the blessed. It is this system which must have inspired Dante's cosmology, and we find in the "Paradiso" (x 98-99) this reference to Albert the Great:

Questi, che m' è a destra più vicino  
Frate e maestro fummi, ed esso Alberto  
È di Cologna

Albert was not entirely satisfied with his cosmological theories, which are sometimes very difficult to follow (see Duhem, "Le Système du Monde", t 3, p 327 sq). He knew that his opinion could not be final when he wrote that "celestial phenomena are so far away from anything we know that we have no means of understanding them perfectly. All we know for certain is that the heavenly bodies are moved by a soul, that is, by a separate substance, an intellectual mover, a unit of intellectual life" ("De Coelo et Mundo", 2, 13).

The belief in the existence of a pure intellect in each heavenly body led Albert to share the current opinion of his time about the influence of the stars on human beings, each intellect having a direct influence over the one immediately following it in the hierarchy of spirits. At the top of the scale, the omniscient and omnipotent mind of God controls the whole of the world, right down to the elements, the compound and the simple bodies. Parallel with this hierarchy of creatures there is a hierarchy of light and a hierarchy of weight: the four traditional elements, earth, water, air, and fire, are thus drawn up in echelons from the heaviest, earth, which is at the bottom or in the middle of things, to water, then air, and finally fire which rejoins the celestial bodies—a conception which reminds one of Anaximander's cosmogony. These considerations on the order in the realm of matter have their equivalent in the realm of spirit: the simplest intellect gives the most perfect motion to the star to which it is attached, and again, the simplest and most perfect intellect has the most adequate knowledge of things, the intrinsic and epistemological power of the various creatures being thus echeloned from the Highest God to the humblest of His creatures. The detailed development of this powerful vision of the

nature of reality allows Albert the Great to state and explain his views about the various provinces of our knowledge: the part played by each natural or spiritual being is thus accounted for according to its place in the hierarchy of God's creatures.

Details about the particular sciences are interesting. In alchemy, for example, Albert himself tried several reactions, describing accurately enough the preparation of nitric acid or, as he called it, 'prime water' or philosophical water to the first degree of perfection, and giving at the same time its principal properties, such as the oxidation of metals and the separation of gold from silver. By combining three parts of prime water with one part of sal ammoniac he obtained the secondary water, the tertiary water is obtained by treating mercury with the secondary water, and the fourth water is the result of the distillation of the tertiary water after it has been left for four days in a vessel covered with manure. This fourth water was very popular among the alchemists of the time, who called it 'philosophers' vinegar', 'mineral water', and 'celestial dew'.

Albert distinguished four 'metallic spirits', mercury, sulphur, orpiment, and sal ammoniac, which could all be used to stain metals in gold or silver. But he warned us that the gold or the silver of the alchemists is not pure gold or silver. In fact, though the theory of a 'materia prima' and the conception of transmutation made chiefly an intellectual and philosophical appeal to him, Albert did not believe in the actuality of transmutation. Thus he wrote in "De Mineralibus" (Bk 3, 9): "Alchemy cannot change metals, but can only imitate them. I have tested alchemistic gold, but after six or seven heatings, it is burned and reduced to ashes." He was the first to use the word "affinitas", in his treatise "De Rebus Metallicis", which was no doubt suggested to him by the views of ancient Greek philosophers current at the time, that chemical reaction is due to a similarity or kinship between the reacting substances, or, as maintained by Hippocrates, that like unites only with like. Thus, said Albert, "sulphur blackens silver and generally burns all metals, because of its natural affinity with them" (propter affinitatem naturæ metalla adurit). It seems also that Albert was the first to call sulphate of iron "vitreolum". His small treatise "De Alchymia" gives a vivid picture of the state of alchemy and alchemists in the Middle Ages, a picture which has been confirmed since by the descriptions of Paracelsus.

In his biological works Albert follows very closely Aristotle's text, given a sentence or two of the Stagyrte and adding his own remarks by way of commentary, in sifting what is Aristotle's from Albert's additions, it has been found that the remarks of the Dominican monk contain a considerable amount of personal observations which prove that he was a naturalist of great ability. In his "Short History of Biology" (pp 73-74), Prof Charles Singer quotes a long passage of Albert's treatise "De Animalibus" in which there are

some striking remarks about embryos of birds and of fishes, while he considers Albert's book "*De Plantis*" as the best work on natural history produced during the Middle Ages. Albert seems to be at a loss, however, in his attempt to draw up any general account of plants, since he reaches no satisfactory basis of classification, and is equally ignorant both of their minute structure and their true mode of reproduction. Yet his descriptions are fairly accurate, and show that he had a remarkable gift of observation.

These general remarks illustrate the range of Albert's knowledge and scientific interests. He probably wrote also on mathematics, as he often refers to his mathematical works, especially the 15th and 16th books of his geometry (in *Met* 2, 1), but these works have not reached us. We know, however, that Albert placed mathematics between metaphysics and natural science, the object of mathematics being defined as the motion and material extension of natural objects independently of their essence and their fundamental causes. The mathematician studies the straight line, for example, as it is materially illustrated in Nature, but he does not consider the cause of the straight line or the particular matter which illus-

trates it. Such considerations were possible, of course, at a time when Euclidean geometry was the only known system in terms of which Nature could be interpreted.

To-day these and the other scientific views of Albert the Great could scarcely bear the strain of a searching criticism. It would be unfair, however, to dismiss Albert's claims to consideration because they do not correspond to the extraordinary developments of modern science. Should one ignore Aristotle or Plato because his biology or his cosmology is behind the present state of science? Every system of philosophy has to give some account of Nature, with reference to the scientific beliefs of the time. None of the great thinkers of the past could have possibly established his doctrines in terms of the science of the future, nevertheless, one studies them as they are and often uses them in the interpretation of modern scientific conceptions. The scientific doctrines of Albert the Great are entitled to a similar consideration, and the historian who devotes his patient efforts to the study of the "*doctor universalis*" will be repaid to the full by the discovery of the valuable indications contained in his writings.

THOMAS GREENWOOD

### The Iron and Steel Industry

MR BOFFIN, it may be remembered, introduced Mr Weg to Mrs Boffin as "the gentleman that's a going to decline and fall off the Rooshan Empire." Prof W A Bone may be introduced as the gentleman who has taken the opportunity, as Melchett metallist of the Institute of Fuel, to decline and fall off our coal and iron industry. Behind the subject he discussed, "*A Century of Fuel Economy*"—in (1) the manufacture of iron and steel, (2) of gas and coke and (3) in the production of power—lies the gradual decay of our iron industry. If European nations agree to disarm, if we continue to develop the use of the road engine, the interest in iron must pass over to nations like Japan and China—to the unsettled East. The topic is, therefore, one of extreme public importance.

Born in a region of coal and raised in the reek of coke-oven, gas-producer and blast-furnace, a lifelong student of the processes, Prof Bone is a man of fuel by instinct, able to envisage and discuss the problems, both of coal and of iron, with detachment and a fullness of ripened knowledge which no other worker, either industrial or academic, has at his command. He is the recognised master artificer in the field of high temperature change, especially in gases. By his recent systematic studies of coal he has revolutionised our conception of its nature. The special department he has developed at South Kensington stands alone and unrivalled in the completeness of its equipment and the accuracy of its apposite inquiries. The Institute of Fuel could not have paid a greater compliment to the man whose memory the medal commemorates, nor have

done a greater service to industrial interests, than it has in making him its metallist and so forcing him to display his knowledge of the subject, which is probably, at the moment, the most important to be considered in the whole range of industrial activity.

The story opens with the downfall, as politician, of the Duke of Wellington, in 1832, and the coincident introduction, by the Scot, J B Neilson, of the hot blast, the first great step in the modern development of the iron industry, signalling the dawn of fuel economy. Neilson appears to have been a most remarkable man and a pioneer in technical education. He had intuitively guessed that the expenditure of a given quantity of fuel (small coal) outside the furnace for the purpose of preheating the ingoing blast would save many times more fuel (coke) inside the furnace. Paradoxical though it seemed at first, trial soon proved him to be right.

The output of Scottish pig-iron rose from 37,500 tons in 1830 to 196,960 in 1839 and to 475,000 tons in 1845. Next came the utilisation of the furnace gases but not until after 1845, when the great Bunsen and his pupil Lyon Playfair reported to the British Association the result of their analyses of the gases, taken at various levels, from a coal-fired blast furnace, pointing out that 81.54 per cent of the fuel was lost in the form of combustible matter, only 18.46 of the whole fuel being realised in carrying out the processes in the furnace. The second invasion of the chemist into the industry was Lowthian Bell's great inquiry (1868-72) into the complex chemical interactions within the blast

furnace Lowthian Bell stands alone as the colossus of the industry—he has yet to be monumentised.

Steel was also advancing. Coincidentally, strange to say, with Perkin's discovery of the first coal tar colour, came Henry Bessemer's invention (1856) of his process, in which iron, taken directly from the blast furnace, was converted into steel by merely blowing air through the molten metal. A great further advance was made, in 1880, when Thomas and Gilchrist substituted a basic for the acid lining of the Bessemer furnace. This, however, threw open the production of iron to the world, as it made possible the use of low grade phosphatic ores, which were previously unworkable. It also greatly aided agriculture, by the introduction of basic slag. It is noteworthy that this advance was practically coincident with that caused by the introduction of azo dyestuffs, which threw the colour industry open to the world. Great Britain's hold upon the colour industry and upon the pig-iron industry waned at about the same time, by no mere coincidence but for similar reasons. Just as we had no second set of workers to compare with the Perkin-Nicholson-Hofmann triumvirate, so we had no second iron and steel triumvirate to compare with the Lowthian Bell-Bessemer-Snelus cum Thomas and Gilchrist combine. Those in commercial charge of both industries were too short sighted to secure the necessary succession of scientific workers: the trained chemist has scarcely been known in the blast furnace industry. Only steel has attracted academic attention. We have recovered our hold upon colour but the blast furnace industry is still lacking in vision and has not put its house in order up to the present day; labour difficulties have been an additional drawback. Prof Bone holds out science as still a key of promise to some further economy in the use of fuel. Users of coal may rejoice at his conclusion but it is one that brings cold comfort to owners and producers. It is imperative, however, that false hopes should not be held out in public in this connexion.

The century of invention Prof Bone discusses is only about fifty years in advance of the beginning of the steel age. Children are taught something of the flint, the iron and the bronze ages, archaeologists gloat over rusty bits of iron found in old Roman foundations yet we look complacently, without wonder, at modern steel defiance of the Tower of Babel legend, this too when our ores are on the verge of exhaustion. Of the many great names mentioned in the course of the address, excepting that of Lord Playfair, scarce one of them is to be found in current literature or the histories—yet they are the men who have made our world what it is. The ministers who figure, for example, in Queen Victoria's "Letters" have been largely automata, owing their importance almost entirely to the backing they have had in coal and steel. Politicians may trumpet their messages from Geneva and Washington but, as Shanghai shows, steel bombs are the messengers which eventually tell in forcing order. The East is too ignorant and too human ever to be reformed by mere talk: the work will need to be helped on by steel in some form.

It is because the story of steel is so ill-told in our schools, so little understood by politicians, that the public to-day has no suspicion of the way in which the world is under ferrous control. If the Highgate Hexaphilites were to name us, we should not be called Calciferites—though we have much lime in our bodies—but Ferrosoferites. Iron is the great social adjuvant, not merely in our blood. Having gone so far in laying bare the statistics of the industry, Prof Bone might with great advantage now prepare the way for a future Mr Weg to decline and fall off the Empire of Coal and Steel, to which the nations, during a century past, have far too exclusively directed their attention. Everything points to a more superficial cultivation of the soil than that involved in mining for iron. Maybe the farmer will yet have his revenge and see iron put in its place, if not in Queer Street—if we no longer build warships, big guns and tanks, if the railways cease to pay because we have taken to the roads and run upon slag rather than upon steel.

The present unhappy state of the British blast furnace industry is deplorable. It was inevitable that we should lose the supremacy we once had and that countries with full command of ore and coal supplies—Belgium, France, Germany, the United States—would both satisfy their own demands and seek to be exporters. It is very doubtful if it will pay us, as long as competition is unrestricted, to supply our own needs, let alone export at a profit. Whether, under a system of regulated fair trade, we shall do so is another question. The art is not one to be lost, as we have no guarantee that the accident of war may not come upon us, moreover, much phosphate is to be gained from our low grade ores. Germany, beyond question, has greatly overbuilt her ironworks—definitely with the object of capturing outside markets. To stop armaments and yet carry on a merciless commercial war in iron will be to create a purely Gilbertian situation.

The rapid development of the American iron and steel industry has been a necessary consequence of the vastness of the continent, the great demand being over, it is unreasonable for the industry to expect that it can be run at full blast at the expense of other countries. The sky-scraper in New York is a logical outcome of the conditions prevailing there—of the limited area at disposal and the existence of Silurian foundations. New York, however, is no excuse for towns in the Far West out on the open prairie. The sky-scraper is simply an American habit. Is it to become one here? We are learning every day more and more to value light—why, then, should we shut it out? We know our English heating system to be more healthy than the Continental and American plan. Everyone who lives in them is beginning to complain of the beehived, graceless constructions now coming into being at the instance of speculative builders. Might we not pause to think if iron after all be worth what it is going to cost us, indirectly perhaps more than directly, in convenience, comfort and health. It has probably too long been our master.

HENRY E. ARMSTRONG

## Obituary

MR GEORGE FORREST

**B**OTANISTS and horticulturists have received with the greatest regret the news of the death of Mr George Forrest from heart-failure, at Tengyueh, in West China, on Jan 5. He was one of the greatest of botanical collectors, and had the good fortune to find the richest of fields for his explorations.

Forrest was born at Falkirk on March 13, 1873, and was educated at Kilmarnock Academy. As a young man he spent some years in Australia and South Africa. Returning to Scotland, he was engaged for a time on herbarium work at the Royal Botanic Garden, Edinburgh. In 1904 came his opportunity. On behalf of Mr A. K. Bulley, of Neston, he made the first of his journeys to western Yunnan to collect plants and seeds. From that time onwards he devoted himself, with but brief vacations, to exploration in Yunnan and the adjoining regions.

The floral richness of the provinces of western China and of eastern Tibet was long unsuspected. A foreshadowing of the botanical wealth of the area came first from the dried collections of Prof. A. Henry and from the material sent to Paris by the French missionaries such as David, Delavay, and Soulié. These noteworthy collectors did not, however, explore in any detail the higher alps of the Tibeto-Chinese frontier, nor did they forward much to Europe in the way of seeds. Consequently, the area was almost virgin country for the horticultural explorer. It was now that Wilson and Forrest, and later Kingdon Ward, Schneider, Handel-Mazzetti, and Rock, entered such a promising field. Wilson had Hupeh and Szechwan for his domain, and "*Plantæ Wilsonianæ*" is testimony to their botanical riches. Forrest was but a year or so later, and chose western Yunnan and the adjoining parts of Tibet and south-west Szechwan. For multiplicity of species this is the richest area in China, and has good claims to possess the finest alpine flora in the world. Forrest made no fewer than eight expeditions into these regions. The number of his dried botanical specimens exceeded 30,000. Many of the species had been found before by the French missionaries and described by Franchet at Paris, but many hundreds were new, and these specially natives of the higher altitudes between 10,000 ft and 15,000 ft.

Forrest kept an even balance between the claims of botany and horticulture. He made it his endeavour to secure seed of all plants of horticultural merit and also of any botanical interest. His dried material forms one of the great collections, worthy of comparison with that of any previous explorer in any country. Apart from copious field notes, the material is of the very highest standard, witness the statement of a Japanese botanist, Prof. Kudo, who has just published, after fifteen years' study, a monograph on the Labiatae of eastern Asia. For that purpose he visited some forty of the chief herbaria in Europe, Asia, and America, and records

of his examination of Forrest's specimens that his collection of Chinese plants is "*die beste in der Welt*" (*Mem. Fac. Sc. Tôhoku Imp. Univ.*, vol. 1, No. 2).

Much of Forrest's success in this respect was due to his capacity for management of the hillmen whom he employed in his travels. These tribesmen were taught by him and became expert in the drying of herbarium material, in the collection of seeds in autumn (implying recognition of what was previously collected in flower—no easy task), and in the skinning of birds and mammals. The hillmen were particularly loyal to him, sometimes travelling six weeks to meet him when they heard he was arriving at Bhamo *en route* for the Chinese Alps. This influence extended to the tribesmen generally, as well as to all classes of Chinese in the towns and villages at lower elevations. Among other kindnesses, he was welcomed for his attempt to do what he could for them in the way of rough-and-ready 'doctoring'. He felt their needs so much that he was in the habit of procuring lymph from Burma, and in his time inoculated many thousands against smallpox. It was only on his first expedition, when feelings between Tibetan and Chinese were exacerbated, that Forrest had serious conflict. That first expedition ended in tragedy. A large party, some eighty in all, including Forrest and two French missionaries (Père Dubernard and another), were assailed by the Tibetans, and only a bare dozen escaped massacre. Père Dubernard was brutally tortured before death, and his companion was killed on the spot. Forrest was hotly pursued for some ten days, without shelter and without food. Of his personal following of seventeen, there was only one survivor.

Though somewhat short of stature, Forrest was of very robust build and was able to endure the roughest of travelling. Unfortunately, he never gave to the world a written record of his experiences in central Asia. Few explorers could have had a more fascinating story to tell, but the task of writing it was always postponed until his days of retirement—and that time did not come. In any event, the task did not appeal to him, and it was only rarely that he could be persuaded to write for publication. His interests lay wholly in the field; his collections of the flora and fauna of the area, supplemented by accurate and very complete notes, have formed the basis of a very large number of scientific papers, while European gardens have been much enriched by the numerous plants raised from the seed secured on his various journeys.

WE regret to announce the following deaths.

Prof. W. Billington, professor of surgery in the University of Birmingham, aged fifty-six years.

Sir Arthur Duckham, president-elect of the Federation of British Industries and one of the founders of the Institution of Chemical Engineers, on Feb. 14, aged fifty-one years.

## News and Views

## Tariff Commission and a Scientific Policy

THE creation of a Tariff Commission, or, as it is called, Import Duties Advisory Committee, as part of the Government's general tariff plan has implications which go far beyond the theoretical merits of 'free trade' or 'protection', and are of special interest to scientific workers. As Capt Harold Macmillan, M.P., points out in recent articles (cf *Week-End Review*, Jan 30, and *Sunday Times*, Feb 14), Britain suffers particularly from the chaotic market conditions which affect all countries, because not only is a large proportion of its production for export, but also because alone among nations it has a home market open to unrestricted competition. In the absence of any protective device, British economic development is being determined not by our own decisions but by the fluctuating disorder of world trade. The old fiscal controversy having now been resolved in principle by the Government decision to apply tariffs to a wide range of manufactures, the question of practice and of the purpose for which tariffs are to be applied becomes of primary importance. It is clear that both ministers and other members of Parliament are now prepared to consider the economic and financial aspects of a tariff policy in relation to the reorganisation, modernisation, and readjustment of industry as part of a definite plan of national and imperial policy. The execution of any such constructive policy, involving the application of scientific methods in this difficult and contentious field, requires a wealth of detailed information regarding the relations between different industries, their productive capacity, efficiency, their importance in the general national economy, the merits of their plans of reconstruction, and so forth.

## Scientific and Industrial Development

THIS information and the essential co-operation of industry can probably only be secured by the creation of representative councils for each of the great national industries, and in this way the Tariff Commission will be brought face to face with rationalisation problems, technical questions of scientific development, industrial organisation, and management. In addition to the technical advice of industrial representatives, the co-operation of the banks, co-ordinated, for example, through some such body as the Bankers' Industrial Development Trust, will be required, since intelligent use of the powers of the Committee involves the complete supervision of every question relating to industrial and commercial development. If the Government proposals are indeed directed towards the evolution of such a deliberately planned national economy, there will undoubtedly occur opportunities of making representations to the Commission upon the scientific position of many of our great industries the development of which is dependent upon technical control and scientific research. It is desirable that the Commission should be aware of what scientific opinion is on such great

industries as the textile industry, the iron and steel industry, etc., and it is incumbent upon representatives of science to follow these developments with the closest attention and to seize the earliest opportunity of making representations or affording other assistance towards the evolution of a creative and scientific national policy.

## Tariffs and Imported Scientific Books

THE text of the Import Duties Bill, whereby an *ad valorem* duty of 10 per cent is to be charged on goods imported into Great Britain, has been issued, and we are glad to see that newspapers, periodicals, and printed books, and radium compounds and ores are among the articles exempted from the impost. As was pointed out in our issue of Feb 6, p 195, the revenue to be expected from a tax on imported scientific literature is negligible, the only effect of such a duty would be to increase the cost of scientific research. It is encouraging to find that this aspect of the matter is appreciated in Government circles, and that, amid the many claims for exemption which have, no doubt, been put forward, consideration has been given to the needs of scientific workers. Affairs do not seem to be so well ordered in Australia. It will be recalled (*NATURE*, Nov 28, 1931, p 900) that the Commonwealth has in force a duty of 10 per cent on imported books and a sales tax of 6 per cent, this, with the depreciation in Australian money, has proved a serious handicap. Incidentally, it has demonstrated our contention that, as a source of revenue, an import tax on books is not worth consideration. However, it is stated by the Canberra correspondent of the *Times*, in a message dated Feb. 11, that a deputation including Sir George Julius, chairman of the Council for Scientific and Industrial Research, has waited on the Prime Minister, Mr Lyons, who has promised to consider the exemption of historical records and scientific periodicals, although he will not consider the early and total remission of the sales tax.

## Discovery and Uses of X-Rays

SEVERAL letters have appeared recently in the *Times* on Prof W C Röntgen's discovery of X-rays and their early use in surgery. As *NATURE* is mentioned by three of the correspondents, it may be worth while to recall the association of this journal with the notices of the discovery. General announcements appeared in the daily Press on Jan 7, 1896, to the effect that Röntgen, who was then professor of physics in the University of Würzburg, had discovered that a number of substances which are opaque to visible rays of light are transparent to waves capable of affecting a photographic plate. A note upon these reports appeared in *NATURE* of Jan 16, 1896 (vol 53, p 253). In the issue of the following week, Jan 23, we published a letter from Sir Arthur Schuster on the physical significance of Röntgen's observations, and Sir Arthur himself arranged for the translation into English of Röntgen's

paper "On a New Kind of Rays" from the *Satzungsberichte der Würzburger Gesellschaft*, 1895, which appeared in the same issue. This, we believe, was the first complete account of Röntgen's work published in England. To the same issue (Jan 23, p. 276) the late Mr A. A. Campbell Swinton contributed an article describing how, "Working upon the lines indicated in the telegrams from Vienna, recently published in the daily papers, I have, with the assistance of Mr J. C. M. Stanton, repeated many of Prof. Röntgen's experiments with entire success", and his article was illustrated by an X-ray photograph of a human hand taken by him with a Crookes tube. In the following three months as many as one hundred and fifty-five notes and original communications upon X-rays and their applications appeared in our columns.

#### Gold Medal for Astronomy

THE award of the gold medal of the Royal Astronomical Society to Dr R. G. Aitken, director of the Lick Observatory, Mount Hamilton, California, was the subject of the presidential address given by Dr Knox-Shaw, Radcliffe Observer, Oxford, at the annual general meeting of the Society on Feb 12. The actual presentation of the medal is deferred until May 13, when the medallist is coming to London to deliver the George Darwin lecture, the subject of this has not yet been announced, but it will probably be connected with double stars. Dr Knox-Shaw began his address by giving a description of the state of double-star astronomy in the middle of the last century, it was taken for granted that the work of the two Herschels and the two Struves had exhausted the mine of possible discoveries, at least in the northern hemisphere, and that it only remained to continue the observation of the known pairs, with a view of obtaining better orbits.

#### Dr Aitken and other Double-Star Observers

WITH the advent of the great American telescopes a new era began. It became possible to detect much closer pairs than before, these offered such a large field that for the first time a distance limit was fixed, beyond which stars should not rank as doubles. This was taken as 5" for stars of the ninth magnitude, but was made wider for brighter stars and for stars of large common proper motion. S. W. Burnham was the first to make a great advance in this direction, in 1906 he brought out a great catalogue of 13,665 pairs, more than two thousand of these being his own discoveries. Dr Aitken has been a worthy successor. With the aid of Dr Hussey, who was his fellow-worker for many years, about four thousand new pairs have been found, and a new general catalogue is in course of formation. An important point is that many of the new pairs are extremely close (separation less than half a second). As was to be expected, many of these close pairs showed fairly rapid motion, in fact, one of them has completed a revolution since discovery, Dr Aitken enjoys the distinction of having made all the observations upon it, and also of computing its orbit. From a physical point of view, the chief importance of double-star astronomy is

the information that it leads to on the masses of the stars. At the beginning of this century not more than a dozen star-masses were known with any accuracy, the number has now been greatly increased, the study of eclipsing binaries having added to it. As a result, Sir Arthur Eddington was able to deduce the law correlating mass with absolute magnitude. This important law rests largely on such work as that carried on by Dr Aitken.

#### Gold Medal of the Hunterian Society

THE Hunterian Society, the oldest medical society in London, offers annually or periodically for competition a medal bearing the profile of John Hunter. It is open to all general medical practitioners resident in Great Britain, Ireland, and the Channel Islands, and is awarded for an essay. The subject of the essay is chosen by the writers from any subject in the medical sciences, and each essay has to be written under a motto or device and is accompanied by a sealed envelope containing the writer's name. In 1931 the Council recommended that the medal should be of gold instead of silver as heretofore, and that a new design should be struck. Accordingly, Mr Thornton Shiells, with Mr H. Youngman, engraver, produced a gold medal the size of a crown piece. The original designs and the plaster medallion made for the purpose are now preserved in the Library of the Society. For the first competition under the new régime a number of essays of high order were received, and the medal has been awarded to Dr Griffith Ifor Evans, 37 Castle Square, Caernarvon, for an essay on "Chronic Familial Syphilis". Dr Gwladys Victoria Smallpiece, of 365 Woodstock Road, Oxford, was declared "proxime accessit". The medal was presented to Dr Griffith Evans at the annual dinner on Feb 11. The next award of the gold medal will be made in 1933 for essays received on or before Dec 31, 1932. The rules governing the award may be obtained on application to the honorary secretary of the Society, Mr Andrew McAllister, 79 Wimpole Street, London, W. 1.

#### Extension of University College, London

UNIVERSITY College, London, has acquired by purchase a site of two acres, formerly occupied by Messrs Shoolbred, immediately south of the buildings of the Faculty of Medical Sciences of the College. This is the largest addition to the site of the College made since its foundation more than one hundred years ago. The site acquired by the founders was some eight acres in extent, and most of the previous additions to the College have been confined to this area. So long as fifty years ago attempts were made by the College to buy the site, on which, eventually, were erected warehouses, depositories, and stables for Messrs Shoolbred. The site was too large for University College to buy or to occupy as a whole. The problem was solved by the Carnegie United Kingdom Trustees, who acquired part of the property as permanent headquarters for the National Central Library and the Library Association. In the College part of the territory there will be housed the Departments of

Zoology and Comparative Anatomy, Botany, Geology, Geography, and Political Economy, and certain other needs will be served there. The Departments moving out of the old buildings of the College will set free accommodation much needed by the Faculty of Arts and by the Libraries. The College has also received a great benefaction for the endowment of the Department of Zoology and Comparative Anatomy from the Rockefeller Foundation. The benefaction amounts to £88,000, and must be devoted to the advancement of research. This gift follows other benefactions by the Rockefeller Foundation, which have made possible the building of the new Department of Anatomy and Embryology and the provision of endowments for that Department and the Departments of Physiology and Pharmacology.

#### British Industries Fair

THE eighteenth British Industries Fair, which will open in London and Birmingham on Feb. 22, will be the largest and most representative display of British manufactured goods that has yet been organised. Last year exceeded all previous efforts, and this year marks a further advance. Following the practice of last year, the Fair will consist of two sections, the London Section and the Birmingham Section. In London the exhibits of the lighter trades and the specifically Empire exhibits will be held at Olympia, the White City will accommodate the display of textiles and clothing, which for the first time will represent all branches of the textile industry. At Castle Bromwich, Birmingham, there will be exhibits mainly of hardware, house equipment, and engineering, and, out-of-doors, an exhibition of agricultural implements and of plant for light railways, quarrying, and roadmaking. The total frontage of the stands in all sections of the Fair will amount to approximately 16 miles. The total number of exhibitors will be 2305, of which 1150 will exhibit their products at Olympia, 130 at the White City, and 1025 at Castle Bromwich. Of the new trade groups that have co-operated in this organised effort to exhibit the variety and extent of British manufactures, mention may be made of the oil section, and of the section for mining, quarrying, and roadmaking plant. The former will provide working exhibits of the latest oil-fired plant, and the latter will give a demonstration of the actual construction of a road. We hope to give, in a subsequent issue, a review of some of the chief features of the Fair.

#### Second Dynasty Burial Rites at Ur

MR. LEONARD WOOLLEY's first report on the current season's work at Ur, which appeared in the *Times* for Feb. 12, chronicles *inter alia* the discovery of a burial of a type "quite out of the ordinary." It has the additional interest that it belongs to the Second Dynasty of Ur, about 2800 B.C., a period and dynasty about which at present nothing is known. The Joint Expedition of the British Museum and the Museum of the University of Pennsylvania is now engaged in endeavouring to trace the earlier history of the sacred area on which stands the famous ziggurat of the Third Dynasty. In the first month's work the complete ground plan of a range of buildings on the

north-west side has been brought to light. The buildings belong to the First Dynasty. The burial to which reference has been made was not discovered here, but in the course of excavating a patch of ground between the predynastic cemetery and the mausoleum of Bur Sin. Eighteen people were found buried at the foot of a rectangular shaft originally at least 20 ft. deep, but of which the bottom is now 30 ft. below the surface. All the bodies, which were bedecked with gold ornaments and beads, had been buried independently, although the burials were contemporary, and the same elaborate ritual had served them all. Above the graves a clay floor had been spread, and on this were fireplaces and a brick-walled enclosure containing traces of food. Above this were two floors, at different levels, with altars, and the shaft was closed finally with rubble and brick packing. Evidently, Mr. Woolley notes, the burial had been by stages, each marked by ceremonies of fire and sacrifice.

#### Co-operation in Archæological Research in France

THE Smithsonian Institution announces the completion of an agreement with the University of Toulouse, whereby the two bodies will co-operate for a period of ten years in the excavation of the cave of Marsoulas in the Haute-Garonne among the foothills of the Pyrenees. The cave is the property of the University, and is already well known to archæologists for its polychrome paintings and wall engravings of palæolithic age. It was first investigated by archæologists in 1886-87, but after that it was comparatively neglected until recent excavation by Mr. J. Townsend Russell of the Division of Old World Archæology of the Smithsonian Institution. The cavern is about thirty metres in extent, but galleries now closed by clay infiltration suggest that at the time of its occupation by palæolithic man it may have afforded more extensive accommodation than at present. It is hoped that it may be possible to open up these galleries. By the time the agreement expires, the cave should be cleared completely. In the meantime the terms of the agreement may be extended to cover other investigations, possibly so far afield as the French Near East and Africa.

#### Recent Excavation in the Marsoulas Cave

EXCAVATION in the Marsoulas Cave during the past season by Mr. Russell on behalf of the Smithsonian Institution has already produced results of importance, which promise well for the future of the joint undertaking. Two ancient hearths were found, of which the upper yielded artefacts typical of the Magdalenian period. Just below was an Aurignacian hearth with typical knives, scrapers, points and decorative pendants of flint and bone. An unexpected find was a triton shell, which must have come from warm water then far to the south, probably from Africa. The technique of one of the numerous wall-paintings observed is described as unique. The animal form had been produced by the thumb of the painter, which had been dipped in the wet pigment and then pressed on the wall. The paintings of the Marsoulas Cave are singular in the fact that they are near the entrance

instead of in the far recesses of the Cave as is more usual. Their excellent state of preservation suggests that the entrance of the cave must have been blocked by an obstruction for a very long period after the close of the palaeolithic age.

#### Cereals for Spring Sowing

THE selection of the best varieties of cereals for spring sowing is always a question of importance for the farmer. To meet this need, the National Institute of Agricultural Botany, Cambridge, has issued a leaflet (*Farmer's Leaflet*, No. 2) describing the varieties most suitable for use in the Midlands, east, and south of England, the recommendations being based on tests carried out at a number of trial stations. The sowing of spring wheat is not, in general, advocated, but of the varieties available, Little Joss is suggested for February and Red Marvel or Al for early March sowings. The choice of oats is, however, much wider. Victory is one of the best all-round varieties, useful both for sale and feeding. Star, an oat similar, on the whole, to Victory, has the additional advantage of a thinner husk and a better standing straw, and is, therefore, preferable on highly fertile soils. Golden Rain and Golden Rain II also deserve consideration when the crop is intended for feeding on the farm, since the colour of the grain is apt to affect the market price adversely. Marvellous is a further variety which usually gives heavy crops, but it is only suitable for early February sowings. As regards barley, the choice lies between the well-established Plumage and Spratt-Archers and the new variety recently produced by Dr Beaven, called Golden Archer. The latter is of the Spratt-Archer type, with similar malting quality, but the yield is rather better. For unusually late sowings, the early ripening Victory is suggested as the most suitable. Early sowing of all spring cereals is regarded as of the utmost importance, irrespective of the variety chosen. In view of the bad harvest conditions of 1931, farmers are advised to pay special attention to germination. The Official Seed Testing Station, Cambridge, undertakes germination tests at the nominal fee of 6d per sample.

#### Selection of Sugar Beet Seed

THE question of the selection of sugar beet seed will soon be receiving the attention of farmers, now that most factories have fixed sugar beet prices for 1932. The results of the exhaustive trials carried out by the National Institute of Agricultural Botany, Cambridge, in recent years, have been reviewed in the light of the new prices, and it can be confidently said that on most soils the heavy yielding (or E types) will pay the farmer better than the high-sugar-content (or Z) types. For general cultivation, Kleinwanzleben E or N, Dippe E, Dobrovice, Hoerning R R, and Zapotil I can all be recommended, Marsters and Johnston's Perfection should be chosen for early sowing, and on very rich land either of these two or Kuhn P. A leaflet describing these strains can be obtained, free of charge, from county organisers, or the Institute, to which application can also be made by those desirous of advice or further information.

No 3251, Vol. 129]

#### Forestry in Kenya

THE Annual Report of the Kenya Forest Department for the year ending Dec. 31, 1930, affords pleasurable reading for all those interested in the progress of forestry conservation and development in the Empire. The whole Colony enjoyed good rains, and a record acreage of new plantations, 4429 acres, was made. Excellent growth both of the new and old plantations was recorded, and there were no forest fires of any consequence. The economic slump, as is a common experience in forestry operations, resulted in a considerable drop in the revenue from timber and from the sale of young trees and seeds. For the first time the revenue from firewood actually exceeded that from timber. This factor alone would justify the far-seeing policy of the Colony's administrators in supporting a correct forest administration. It is of interest to note that the management of the intensively worked forests of the Nairobi District was placed on a satisfactory basis during the year by the completion of detailed working plans. The Chinese tung oil tree, *Aleurites Fordii*, has been previously alluded to in NATURE, and it was mentioned at the time that experiments were being carried out to ascertain the possibilities of growing the tree commercially in several of the Colonies. Great interest is being shown in this tree by farmers in Kenya, and the Forest Department has acted as agent in the distribution of the seed. A few experimental trees have been planted, since it was first grown in the Department's arboretum in 1922, at practically every forest station, to test the suitability of the various districts, but the trees are as yet too young to give definite indications.

#### A Modern Telephone Cable

IN January 1931 a telephone service was inaugurated over a new submarine cable spanning the hundred miles between Key West, United States, and Havana, Cuba. The new cable is the longest deep-sea telephone cable in the world, and it is unique in having neither intermediate repeaters nor inductive loading. A paper describing its engineering characteristics was read by H. A. Affel, W. S. Gorton, and R. W. Chesnut at the winter convention, held in January, of the American Institute of Electrical Engineers. The new cable can operate at a frequency of 28,000 cycles a second, which is about eight times faster than ordinary cables. The feature of the new cable which has made this great improvement possible is the use of paragutta, the new insulating material invented at the Bell Telephone Laboratories. There are three telephone channels in the cable, obtained by an adaptation of the ordinary carrier apparatus used for long distance transmission over open wire lines. There are six frequency bands, one for each direction in the three channels. The largest skin effect occurs in the central conductors, but the effect is also noticeable in the thin return copper tapes. Elaborate precautions were taken to prevent 'noise' intruding in the speech circuit. Frequency limiting filters were introduced into several neighbouring circuits and proved effective. If traffic requirements grow so that more facilities are required, a higher frequency range can be employed.

and additional channels obtained. In addition, if telegraph circuits are required, carrier telegraph systems may be operated in place of one or more of the telephone channels. For example, with the six telephone channels, a possible arrangement would be to employ two of these channels for carrier telegraph circuits. The cable could then carry simultaneously a load of four telephone messages and twenty-four or more two-way telegraph messages.

#### Medical Uses of Radium

THE Medical Research Council has issued a report which summarises the results of research work in the treatment of cancer done during 1930 by means of radium salt entrusted by H.M. Government to the Council (*Special Rep. Series*, No 160 London: H.M. Stationery Office 1s net). It also contains data concerning patients treated in earlier years, and thus maintains continuity with the eight previous and similar reports that have been issued. The stock of radium entrusted to the Council has been distributed on loan to selected research centres throughout Great Britain. Growths of the breast, cervix uteri, and buccal cavity are at present most favourable for radium therapy, but in rectal growths little success has attended the treatment. It is remarked that up to the present no method has been discovered by which malignant cells can be made more radium-sensitive, and that any advance in this direction would have wide-felt effects. Of cases of sarcoma, 23-50 per cent react favourably to radium treatment, and five cases of brain tumour have been treated, with two apparent successes.

#### Physiology and the 'Aura'

IN our issue of Feb. 6, p. 197, a note was published referring to Prof. D. F. Fraser-Harris's paper at a recent meeting of the British Psychological Society, in which he described the so-called human aura as the familiar negative after-image produced by temporal retinal induction. Dr. F. W. Edridge-Green has written pointing out that the phenomenon can be shown with white cardboard, and that it and "numerous others of a similar character are due to the movement of the photochemical fluid in the interretinal space. There appears to be a continuous flow towards the centre of the retina when the eyes are being used." We may add that Prof. E. N. da C. Andrade gave a humorous description of some experiments on this subject in *NATURE* of Dec. 23, 1922, p. 843. Prof. Andrade used his hand and also cardboard hands and figures, and his conclusion was that the effects were due to after-images, an explanation given of a similar experiment referred to by Dr. Edridge-Green in *NATURE* of Dec. 9, 1922, p. 772.

#### Palæontological Expedition to Northern India

It is reported by Science Service that an expedition organised by Yale University under Prof. Hellmut de Terra is proceeding to Northern India with the object of investigating the geology and palæontology of the Salt Range, one of the smaller mountain ranges of Northern India, situated about eighty miles south of the Himalayas. This range, which is con-

sidered by some to be one of the key positions of Asia in the geological sense, is an area of great promise for these branches of research, as it has never been examined systematically for palæontological evidence. The expedition, it is hoped, may find there evidence bearing on the development of man. The members of the expedition, beside the leader, are Mrs. Hellmut de Terra, Prof. G. E. Hutchinson, and Mr. George E. Lewis.

#### Announcements

At the anniversary meeting of the Royal Astronomical Society, held on Feb. 12, Dr. H. Knox-Shaw, Radcliffe Observer, Oxford, was re-elected president of the Society, and the new members of Council elected were Mr. C. R. Davidson, Sir Arthur Eddington, Mr. John Evershed, and Dr. R. Stoneley.

It is announced in *Science* for Jan. 22 that the Richards Gold Medal for conspicuous achievement in chemistry has been awarded by the North-Eastern Section of the American Chemical Society to Prof. Arthur A. Noyes, director of the Gates Chemical Laboratory of the California Institute of Technology, Pasadena. The Richards Medal, which has thus been awarded for the first time, was established in 1929 to commemorate the contributions to chemistry by the late Prof. Theodore W. Richards, who was professor of chemistry in Harvard University. A trust fund of 10,000 dollars has been raised to endow the medal.

We have received a copy of a new catalogue of Zeiss surveying instruments from Messrs. Carl Zeiss, Mortimer Street, London, which includes details and illustrations of a number of levels, tachemeters, and theodolites, including the new Zeiss theodolite, type III. It is claimed that this instrument shows several improvements on previous models. The weight complete is only seventeen and a half pounds.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A lecturer in pharmaceuticals at the School of Pharmacy, Chelsea Polytechnic.—The Principal, Chelsea Polytechnic, Manresa Road, S.W.3 (Feb. 24). An assistant aircraft inspector under the Government of India.—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (Feb. 25). A lecturer and instructor at the Royal Air Force Electrical and Wireless School, Cranwell, with knowledge of alternating current work and its application to high-frequency engineering.—The Secretary, Air Ministry (Feb. 27). A full-time teacher in the Department of Mathematics and Physics of the West Ham Municipal College.—The Principal, West Ham Municipal College, Romford Road, Stratford, E.15 (Feb. 27). A head of the Mechanical Engineering Department of the Coventry Technical College.—The Director of Education, Council House, Coventry (March 3). A professor of philosophy in the University College of North Wales, Bangor.—The Secretary and Registrar, University College of North Wales, Bangor (May 14).

### Nomenclature for Lines in the $\beta$ -Ray Spectra of Radioactive Bodies

I HAVE found on several occasions considerable trouble and confusion occurring owing to the absence of any system of nomenclature for the lines in the  $\beta$ -ray spectra of the radioactive bodies. These spectra consist of a great number of lines formed by homogeneous groups of electrons, and in nearly every case they have been analysed by means of a magnetic field. The quantity, therefore, that is determined experimentally is  $H\rho = m_0 c \beta \sqrt{1 - \beta^2}$ , where  $\rho$  is the radius of curvature of the  $\beta$ -particle in a magnetic field of value  $H$ , and  $m_0$ ,  $c$ , and  $\beta$  have the usual significance. The quantity that is needed in most theoretical discussions is the kinetic energy of the  $\beta$ -particles, and this is obtained by calculation from  $H\rho$ . When it has been necessary to specify a particular line, it has been usual to give either the  $H\rho$  value or the energy, the latter being expressed sometimes in ergs and sometimes in electron volts. Thus, statements such as "the line  $H\rho$  1410" or "the line of energy  $1.529 \times 10^6$  volts" are current everywhere in the literature of the subject.

This might be practicable if these values of  $H\rho$  and energy for a particular line were likely to remain the same, but the reverse is the case. There is probably no  $\beta$ -ray line for which we know the  $H\rho$  value to one part in a thousand, and the calculation of the energy involves  $e/m$ , giving again a possibility of change in the final result. Almost every research on these spectra introduces slight improvements in the  $H\rho$  values, and this will probably be even more prominent in the future, now that the importance of these spectra in nuclear problems is apparent. We are therefore liable to meet statements about a line  $H\rho$  2916, with a footnote to the effect that this is the  $H\rho$  2913 measured by 'X' a year previously. Further, from the energies of the  $\beta$ -ray groups it is possible to determine the energy of the  $\gamma$ -ray responsible for them by conversion in one of the electronic states, and such  $\gamma$ -rays are referred to either by their energy values or wave-lengths, which are similarly subject to continual change.

Now, a  $\beta$ -ray line and a  $\gamma$ -ray are perfectly definite things, and it is highly desirable that each should be named. Any writer in the subject could then specify without ambiguity the  $\beta$ -ray line or  $\gamma$ -ray to which he is referring, and could state the  $H\rho$  or energy which he considers best to assign to it. The question of what nomenclature to adopt is a difficult one. Since one  $\gamma$ -ray can in principle produce as many  $\beta$ -ray lines as there are different electronic states in the atom, it might appear best to name the  $\gamma$ -ray, say,  $G$ , and then specify the  $\beta$ -ray group  $GK$  to mean that group due to conversion of this  $\gamma$ -ray in the  $K$ -level. I am not in favour of such a system, because the origin of all the  $\beta$ -ray lines is not known, and there is even a possibility of a change in the cases where we think we know the origin. I am, also, not even in favour of

attempting to group all the lines due to a certain radioactive body under one system of nomenclature, because there are numerous cases of  $\beta$ -ray lines of the existence of which we are quite certain, but where there is considerable doubt about which of two bodies actually emits them.

I think it would therefore be best to name on a common basis all those  $\beta$ -ray lines obtainable from the most usual sources. For example, I would suggest that all the lines obtainable from a source of thorium-B in equilibrium with its products thorium-C, thorium-C', and thorium-C'' be grouped together, radium-B plus the radium-C bodies would form another group, and so on. This may not be quite so convenient as endeavouring to effect a smaller subdivision, but it will avoid continual annoying changes in the naming of the weaker lines.

As regards the actual method of naming the lines, I suggest one that is based on intensities, but since we are deliberately using no quantitative data, any method which is proposed must depend on a certain amount of arbitrary choice.

However, I do not think it would be difficult to go through any spectrum and classify the lines relative to their neighbours, and as a basis of classification I would take the direct appearance of the photographic plate when suitably exposed for that region of the spectrum, and call the lines prominent, fairly prominent, or less prominent, irrespective of their

FIG 1

absolute intensities measured in the number of electrons in the line per unit exposure. The prominent lines I would name with capital letters in the order of increasing  $H\rho$  throughout the spectrum. The fairly prominent lines would be named by small letters but with reference to the prominent line next lowest in the  $H\rho$  scale—that is, the first line after the prominent line  $D$  would be called  $Da$  (see Fig 1) and the next  $Db$ , and so on, and then on the farther side of  $E$  the same type of line would be named  $Ea$ ,  $Eb$ , etc. For the remaining lines, numerals could be used within each division defined by the more prominent lines—thus, the significance of  $D1$ ,  $Da1$ ,  $Da2$  is obvious. I think it is a fair assumption that any new lines that are detected will be very faint, and they can easily be named by employing a decimal notation. For example,  $Eb2.1$  would mean a line lying between  $Eb2$  and  $Eb3$ . I think this system would work well if the initial assignment of letters is done so as to provide a large number of divisions in the spectrum.

I am indebted to Dr Feather for the suggestion that certain groups of capital letters should be assigned to definite regions of the spectrum, even if there are not sufficient prominent lines to use them all. A rough idea of the speed of a group would then at once be obtained from its name. For example, letters  $A$ - $F$  might be reserved for lines up to  $H\rho$  1500,  $G$ - $K$  for  $H\rho$  1500-2500,  $L$ - $P$  for  $H\rho$  2500-4000,  $Q$ - $U$  for  $H\rho$  4000-7000, and  $V$ - $Z$  for above  $H\rho$  7000. A  $\gamma$ -ray could, of course, be named in a natural manner

by prefixing  $\gamma$  to the name of the most intense  $\beta$ -ray line for which it was responsible

I am convinced that this question, while perhaps at first sight trivial, is, on the contrary, urgent and important, and that a suitable decision now will save a great deal of trouble in the future. I do not lay great stress on the particular method I have proposed, and should be only too willing to adopt any other method that seems likely to offer more advantages

### Crystal Structures of Vitamin D and Related Compounds

I HAVE had the opportunity of examining by X-rays the crystals of ergosterol and certain of its irradiation products, recently described by a team working at the National Institute for Medical Research.<sup>1</sup> Though the results are only preliminary, they seem of sufficient interest to warrant publication at this stage. Five substances, all of composition  $C_{27}H_{41}OH$  or  $C_{27}H_{43}OH$ , have been examined, with the results shown in the accompanying table.

The most striking features of the crystals are their essential similarities of properties and the simple

more than one molecular species and is purely of geometrical intermolecular origin.

2 The molecule of ergosterol and its photo-derivatives has the approximate dimensions  $5 \text{ \AA} \times 7.2 \text{ \AA} \times 17\text{--}20 \text{ \AA}$ . These form a double layer similar to those of long-chain alcohols and acids. Such dimensions are difficult to reconcile with the usually accepted sterol formula

which would lead to a wider and shorter molecule, but agree much better with one where the carbon chain is attached to atom 17 in ring IV,

3. The rings lie approximately in the  $bc$  plane,

| Substance                                     | $a$  | $b$  | $c$  | $\beta$ | $c \sin \beta$<br>$=d_{001}$       | Space Group     | No of Mol per Cell | No of Mol in Asymmetric Unit | Orders of Basal Plane, Estimated Intensities |    |    |   |    |    |    |    |    |    |

N B—Letters for intensities vs, very strong, mw, medium weak, etc

relation between their unit cells. All the substances except lumisterol occur in platy crystals of a long-chain paraffinoid type. All are monoclinic and show a distinct tendency to elongation along the  $b$ -axis (In lumisterol the crystals are fine needles with  $b$  as needle axis). All are optically positive with (010) as optic axial plane and the fast direction  $\gamma$  inclined at a moderate angle to the  $c$  face. All have the same  $b$  axis of  $7.2 \text{ \AA}$  and their  $a$  and  $c$  axes are simple multiples of  $10 \text{ \AA}$  and  $20 \text{ \AA}$  respectively. The spacing of the  $c$  plane is remarkably constant at  $35.5 \text{ \AA}$ , agreeing with the value found by K. Wejdling and E. Backlin.<sup>2</sup> It differs significantly from that of cholesterol, which was examined for comparison. Lumisterol has a halved  $c$  spacing, and  $\alpha$ -dihydroergosterol, owing to the presence of alcohol of crystallisation, deviates from the others.

From these observations certain conclusions can be drawn.

1 The unit cell of the molecular compound calciferol-pyrocalciferol contains four molecules of each kind, which is the number the symmetry demands for the space group  $C_{27}^3-C2$ . This proves either that calciferol is a simple substance or that it contains other substances indistinguishable by X-rays. The former conclusion is far the more probable. The association of molecules found in the other cases consequently does not show that any of them consists of

that of the larger refractive indices  $\beta\gamma$ , and their width  $7.2$  is approximately constant in all the compounds. This is borne out by the observations of sterol films by N. K. Adam,<sup>3</sup> who finds the molecule area of  $36 \text{ sq \AA}$  for ergosterol, as against  $35 \text{ sq \AA}$  in the solid crystal.

4 The differences between the compounds is due to a difference in the side groups or linkages in the rings, leading to a different form of association in the solid and to a small but distinct redistribution of scattering matter along the chain lengths, as shown by the intensities of the  $c$  plane spectra. The greatest similarity is shown between ergosterol and calciferol, the chief difference being a double association of molecules in the latter case. It may be significant that while the basal plane intensities of ergosterol and dihydroergosterol are practically indistinguishable in spite of the notable difference in spacing, those of ergosterol differ from them particularly in the third and ninth orders. This would seem to indicate that the change had affected the carbon skeleton, not merely the position of double bonds in the molecule. In lumisterol and pyrocalciferol the change in intensities is so much greater that the resemblance is almost obliterated. It is doubtful, however, in view of the extreme complexity of the molecules, whether any conclusive evidence of the actual intra-molecular change can be found by X-rays alone. The most

hopeful method would seem to be the examination of the ultra-violet absorption and Raman spectra of single crystals with polarised light at liquid hydrogen temperatures

### Distribution of Electrons in the Aromatic Nucleus and the Early Stages of Aromatic Substitutions

IN a recent memoir<sup>1</sup> E Huckel has made an interesting attempt to apply modern mathematical and physical conceptions of the electron in valency bonds to an *a priori* deduction of the distribution of negative electricity in the benzene ring and ultimately to the development of a theory of orientation in aromatic substitutions. The paper has been very favourably received by physicists and also by many physical chemists, who have no doubt assumed that the *dénouement* in its main outlines is in harmony with the views of organic chemists. This is, however, not the case, so far as we are concerned, we expected conclusions to be reached which are the opposite of those arrived at by Huckel. Where this author postulates an excess of electrons we consider there is a defect, and vice versa.

It should be stated that we are confining our attention to the reactive positions, and the remarks made in this note are not intended to apply to the circumstances of any of the other carbon atoms in the nucleus. Thus there is little chemical evidence for the alternation proposed by Huckel, even if all the signs are inverted. The theory of Huckel requires that, of two carbon atoms, the one which is the more deficient in electrons will be the more prone to undergo substitution (for example, nitration, sulphonation, or halogenation). The mechanism propounded is initially extrusion of a proton by the relatively *positive* centre, followed by attack of the vacant position by the reagent. On the other hand, we say that the reagent (of the electron-seeking kind, as in the processes specified) attacks the centres of *electron excess*, and that this is followed by the expulsion of the proton.

Our theoretical systems, though not identical in every respect, have been found successful in correlating certain important generalisations in organic chemistry with the changes observed in the properties of inorganic compounds as the charge on the nucleus of the central element alters  $B \rightarrow C \rightarrow N$ ,  $P \rightarrow S \rightarrow Cl$ . They have also proved useful in the interpretation of organic chemical phenomena of the most varied types.

The arguments that could be brought to bear on the present subject are accordingly very numerous, and it will suffice to mention the following three points.

(1) Any theory of aromatic substitution is inadequate if it fails to take account of the fact that the influence of groups on the course taken by substitution in the aromatic series can be perfectly correlated with the effects of the same groups on the orientation of additive reactions of non-aromatic unsaturated substances. Such reactions obviously obey the same fundamental laws as those that govern aromatic substitution and yet the *expulsion of a proton does not occur at any stage of the process*. We claim that in both cases the reagent seeks the centres of greater electronic density.

(2) From a study of the relative strengths of acids and bases, it is known that certain substituents have the effect of loosening the grip of a molecule on a proton, others tighten it. Clearly, in Huckel's theory the groups that make an acid stronger and a base weaker should, when introduced into the benzene molecule, facilitate the process of further substitution. Thus nitrobenzene should be *more* reactive than benzene, whereas toluene should be *less* reactive. Actually the reverse is the case, and circumstances, which from all analogies must assist in the process of extrusion of protons, do not render aromatic substitutions more facile, but, on the contrary, they make them much more difficult.

(3) Even in aromatic substitutions, the proton which is expelled may be detached from a part of the molecule remote from the point of attack of the reagent and of attachment of the new substituent. An example is the perhalogenation of certain phenols and in general all that numerous class of reactions leading to blocked hydroaromatic types. In these cases it is not the atom suffering loss of a proton that receives the substituent, and therefore Huckel's theory could not be applied without such modifications as would amount to a reversal of the principle.

Without, therefore, going into the minutiae of the special organic reactions concerned, we venture to think that the above considerations render the view of Huckel untenable.

Unfortunately, the postulated distribution of electrons in the nucleus must stand or fall with the theory of substitutions, and we therefore assume that some error has crept into the discussion, the mathematical physics of which we are not competent to criticise.

The above remarks apply only to the course of ordinary aromatic substitution, which most organic chemists agree in attributing to the active intervention of unsaturated systems of two or more carbon atoms, substitution in saturated carbon compounds is quite a different phenomenon and may well be preceded by the loosening of the proton replaced. In this connexion the suggestion is not at all novel. Furthermore, cases in which aromatic substitution occur with great difficulty may perhaps be correctly described as of saturated hydrocarbon substitution type, a possible example being the conversion of *m*-dinitrobenzene into trinitrobenzene.

Nevertheless, the theory of substitutions in saturated compounds has not yet been satisfactorily treated, and we do not claim that the idea of incipient proton dissociation is proved in any one example, there are too few reliable data and the evidence is conflicting.

The object of this note is to direct attention to our opinion that the conclusions reached by E Huckel regarding the distribution of electrons in benzene derivatives and the mechanism of substitution are quite unacceptable.

### Surface Tension of Soap Solutions

PROF MAHAJAN's latest letter<sup>1</sup> and his paper<sup>2</sup> suggest that he has entirely misunderstood, not only my own work and the conclusions derived from my experiments, but even the very meaning of the terms dynamic and static surface tension.

The methods used by Prof Mahajan for the

measurement of surface tension are quite incapable of giving a true value of dynamic surface tension, as this requires the measurements to be made in about 0.1 second, or less, especially when small and rapidly moving molecules, such as those of sodium oleate, are concerned. Therefore, what Prof Mahajan terms 'dynamic values' are nothing but *semi-static* values, more or less close to the real static value corresponding to the veritable equilibrium. I have published the results of certain experiments made on solutions of pure sodium oleate<sup>3</sup> at the concentrations 1/25,000, 1/50,000, 1/100,000, which show very plainly that, when the surface tension is measured very rapidly (ten successive determinations were made in the first minute), the dynamic value for a solution in which the active molecules are as near as possible of a homogeneous distribution, is very near that of pure water. Had it been possible to measure the surface tension in the first one hundredth of a second or so, the value would have been identical with that of water. As it was, the following values were obtained:

| Concentration                        | 1/25,000 | 1/50,000 | 1/100,000 |          |
|--------------------------------------|----------|----------|-----------|----------|
| Dynamic (immediately after stirring) | 68.0     | 71.0     | 71.0      | dynes/cm |
| After 15 sec                         | 64.0     | 70.0     | 70.0      | 22°      |
| " 30 "                               | 58.0     | 68.0     | 69.0      |          |
| " 1 min                              | 42.0     | 63.0     | 68.0      |          |
| " 2 "                                | 39.0     | 52.0     | 64.0      |          |
| " 3 "                                | 38.0     | 41.0     | 61.0      |          |
| " 5 "                                | 37.0     | 37.0     | 55.0      |          |
| Static value after 12 min            | 36.6     | 35.0     | 32.1      |          |
| After 2 hours                        | 36.6     | 35.0     | 32.1      |          |

It is obvious that, as the concentration increases, the initial value (dynamic) will be lower. It requires less time for the molecules to become adsorbed in the surface layer, as they are closer to it, and in larger number. Consequently, if we deal with solutions of, say, 1 per mille, or 1 per cent, the measurement must be done in a small fraction of a second in order to correspond to that of water, as the 'drop' is very rapid. I hope I have made it clear that the important drop in surface tension, which, for technical reasons, can only be followed step by step in the case of dilute solutions, is due to the Gibbs-Thomson adsorption of active molecules in the surface layer.

When Prof Mahajan mentions surface tension values of the order of 30-40 dynes, he cannot use the term 'dynamic', as most, if not all, of the adsorption in the surface layer has already taken place. What is meant by 'time-drop due to adsorption' is precisely the phenomenon which has brought the surface tension down from 73 dynes to a value around 30 dynes.

What Prof Mahajan therefore observes is an additional phenomenon, of small amplitude, which takes place *after* the Gibbs-Thomson adsorption, which Prof Mahajan seems to ignore altogether, has played its part.

I take this opportunity to advise Prof Mahajan against quoting the values of surface tension to the third decimal point. After more than ten years of experience with all possible methods of measurements, I have come to the conclusion that the second decimal point is generally dubious when dealing with pure liquids, and is absolutely meaningless in case of colloidal solutions.

### Stokes's Formula in Geodesy

STOKES in his "Collected Papers", vol 2, p 168, gave a very elegant formula, giving elevation  $N$  of geoid above its reference spheroid in terms of  $g$ -anomalies.

The formula is  $N = \frac{R}{G} \int_0^\pi (\Delta g)_\psi F d\psi$ , where

$$F = \frac{1}{2} \left\{ \operatorname{cosec} \frac{\psi}{2} + 1 - 6 \sin \frac{\psi}{2} - 5 \cos \psi - 3 \cos \psi \log \sin \frac{\psi}{2} \left( 1 + \sin \frac{\psi}{2} \right) \right\} \sin \psi,$$

$\psi$  being the angle between current point and the point at which rise has to be calculated. The formula has been neglected so far probably on account of paucity of  $g$ -observations, as it requires for calculation of  $N$  at one place, the values of  $g$ -anomalies all over the globe. Recently, however, it has been brought into prominence by articles by V Meinesz<sup>1</sup> and by W D Lambert<sup>2</sup>.

The former goes so far as to say that it can be used for giving local deviations of geoid. While one may be able to use it to get a general idea of elevation of a broad feature of continental extent, and with luck to get differential elevations of two close points above spheroid, I believe it will never be possible to use it for getting absolute elevations.

For computational purposes it is best to divide the earth into concentric rings round the station, and then we get

$$N = \frac{R}{G} \Delta \psi_0 \Sigma F_1(\psi) \Delta g_M,$$

where  $\Delta \psi_0$  is the breadth of a ring,  $\Delta g_M$  is the mean value of  $\Delta g$  in that ring, and  $F_1(\psi)$  is the mean value of  $F(\psi)$  in that ring.

From this the effect of the various zones for  $\Delta g = 0.001$  cm/sec<sup>2</sup> is given in Table 1.

TABLE 1

| Zone  | $N$ in ft | Zone    | $N$ in ft |
|-------|-----------|---------|-----------|
| 0°-2° | +1        | 70°-80° | -4        |
| 2-4   | +1        | 80-90   | -4        |
| 4-6   | +1        | 90-100  | -3        |
| 6-8   | +1        | 100-110 | -1        |
| 8-10  | +1        | 110-120 | 0         |
| 10-20 | +4        | 120-130 | +1        |
| 20-30 | +3        | 130-140 | +2        |
| 30-40 | +1        | 140-150 | +2        |
| 40-50 | -1        | 150-160 | +2        |
| 50-60 | -3        | 160-170 | +1        |
| 60-70 | -4        | 170-180 | 0         |

The figures in this table are correct to the nearest foot.

In actual practice, to get mean  $\Delta g$  in each zone, we will have to divide these zones into smaller compartments, and calculate the mean  $\Delta g$  from each of the compartments and then deduce the mean  $\Delta g$  with its probable error for the whole zone. While near the station the probable error of the mean  $\Delta g$  in our zones may be of the order of 0.005, in outer zones it may easily attain a magnitude of 0.01. These probable errors will enable us to assess the maximum error in our estimated  $N$ . A probable error of 0.01 in zone 60°-70° will mean that our estimation of the share of that zone in producing rise of geoid may be wrong by, say, 40 ft. A systematic error of 0.01 in zones from 40°-100°, and of -0.01 in zones from 130°-170° would vitiate the results hopelessly. In no case could one say with any reasonable certainty that  $N$  at a station was correct to even 100 ft or 200 ft.

For differential purposes, however, the situation is different. The effect of error in each compartment,

especially for the distant zones, is practically the same for two nearby stations. If, then, we have got a map of the world with our estimated  $\Delta g$ 's, we could by suitable templates in a manner analogous to Hayford's isostatic reductions read off the mean  $\Delta g$  for our rings, and probably get a reasonable answer for the differential heights of the points in a local area.

Hence, although the validity of the formula, which was doubted by Helmert, is unquestionable, as V Meinesz proves, it must be realised that for countries of such wide extent as India, where the elevations of geoid above its spheroid of best fit, as indicated by plumb line deflexions, are of the order of only 20 ft., it is not likely to be of much use, as the uncertainty of the value of  $\Delta g$  in the outer zones makes it impossible to attain this order of accuracy.

### The Zodiacal Light and the Luminosity of the Night Sky

THE spectrum of the zodiacal light was photographed by Fath,<sup>1</sup> who found that it showed the Fraunhofer line *G* and a blend of *H* and *K* lines, and did not show indication of any bright line. He concluded that zodiacal light is reflected sunlight. I have recently obtained photographs of the spectrum of zodiacal light on very clear nights at Poona (lat 18° 31' N) with an F/1.5 glass spectrograph constructed locally (with the kind assistance of Mr S P Venkateswaran). Using Mimosa extreme orthochromatic plates (H and D for light from half-watt lamp 2600), which I have found to be the most rapid for this work, the spectrograph is sufficiently powerful to bring out the night sky line 5577 Å in one hour's exposure with a slit-width of 0.7 mm.

When the spectrograph is turned towards the zodiacal light at an angle of about 25° above the horizon and successive photographs (each exposure lasting one hour or one hour and a half) taken on the same plate, beginning when the sun is about 20° below the horizon, it is found that the line 5577 Å comes out strongly, and with the decrease of intensity of the zodiacal light the line also becomes fainter. The intensity of the light decreases to about a third between 8 P.M. and midnight in December, and remains more or less steady thereafter.

It may be mentioned that the brightness of the continuous background in the zodiacal light is too small to affect the above conclusion. In the northern and southern skies, the intensity of the green line is more or less steady, with some slight variations which are under investigation. The midnight maximum noticed by McLennan and collaborators, and by Lord Rayleigh, is not unambiguously evident in these latitudes.

The above observations raise the question whether the luminosity of the night sky and of the zodiacal light are not identical in origin. The presence of the green line 5577 Å in the zodiacal light, and hence of atomic oxygen at great distances from the earth, are particularly interesting from the point of view of theories of the origin of zodiacal light.<sup>2</sup>

Photometric measurements to decide the issues raised above are in progress.

### Polish on Metals

WE are much interested in Mr French's letter in NATURE of Jan 30, as we ourselves have just constructed an electron camera for the examination of the polish on metals and similar problems. In an earlier paper by Prof G P Thomson<sup>1</sup> it has been stated that no pattern was detected from polished metal surfaces, and it was felt at the time that this result was not in accord with other work then proceeding in this laboratory. It had been found<sup>2</sup> that so-called amorphous substances, such as glasses of widely differing chemical compositions, gave rise to very definite X-ray diffraction patterns which bore strong similarities to the line patterns of corresponding crystalline substances. This led us to the view that, while glasses may contain some material in a truly amorphous form, the greater number of atoms are built up in the form of exceedingly small crystals, probably not exceeding 10<sup>-6</sup> cm in size. At the same time, small differences were noted between the spacings of the diffuse bands of the vitreous substance and those of the corresponding completely crystalline substance.

It had already been shown theoretically<sup>3</sup> that the atoms in the surface layer of a crystal have a slightly

FIG 1—X-ray photographs of graphite and 'amorphous' carbons

different spacing from those in the layers beneath, and Prof Lennard-Jones was then able to show<sup>4</sup> that the spacings of exceedingly small crystals, of the size of those found in glasses, could differ from those of the ordinary crystalline material by several per cent.

In view of this, and assuming that Mr French's bands are of very similar spacings to two of the lines of the ordinary copper pattern, a slightly modified interpretation of his results becomes possible. When a metallic surface is polished the crystals break down into smaller units, causing the diffraction pattern to become slightly diffuse. As the polishing proceeds, the crystals break up into still smaller units, so that the interplanar spacings also alter. At the same time, no doubt, a certain amount of truly amorphous material may be produced. This would tend to fog the diffraction pattern still more, so that the weaker bands would become very indistinct, if not impossible to see.

It does not necessarily follow that because the diffraction pattern of the polished surface does not contain the same number of bands as the crystal pattern does lines, that the two lattices are not essentially the same. This point is emphasised in the accompanying series of X-ray photographs of graphite and 'amorphous' carbons (Fig 1). It is not meant to discuss these in detail here, but it will be seen that

the outer diffuse line of photograph (2) has almost disappeared in (3) and cannot be distinguished in any of the remaining photographs\*. Further, measurements show that as the crystal size decreases, the basal plane (002) spacing increases, while the (100) spacing decreases at a lesser rate. This general trend can be seen in the photographs. Such changes of spacing had already been noticed,<sup>5</sup> but we think the present series of photographs gives rather a convincing demonstration of the gradations between a truly crystalline substance and one which would formerly have been called amorphous. It must also be remembered that the shape of the ultimate crystallites of the polished surface will have a bearing on the relative intensities of the bands.

### Mechanism of Racemisation

IN some work shortly to be published, we have shown that the racemisation of Rochelle salt by caustic soda is accompanied, and probably conditioned, by complex formation. It was previously observed by Thomsen,<sup>1</sup> and confirmed by Winther<sup>2</sup> and by ourselves, that the rotation of sodium tartrate is reduced by the addition of alkali. We have, therefore, in continuation of our work on racemisation, investigated the behaviour of the specific rotation of Rochelle salt with increasing concentrations of alkali, and we find that the specific rotation of Rochelle salt eventually becomes strongly negative. In other words, the complex is itself *lævo*-rotatory, and the progressive reduction in the rotation is due to increasing formation of complex with addition of alkali. The rotation changes sign at an alkali concentration of 10 *N* caustic soda (approx.). It should be stressed that these changes of rotation are prior to any racemisation, in the ordinary sense of the term, the rotations being quite stable in the strongest alkali, provided the solutions are kept at room temperature.

If, as we suppose, the complex is produced by the entrance of sodium atoms in place of the hydrogens of the radicle OH-groups, it appears that interchange of groups takes place, immediately on dissolving in alkali, if we accept the usual hypothesis of the mechanism of racemisation. On this view, the subsequent process of heating to produce racemisation is merely one of stabilisation to prevent the converse interchange of groups on acidification. This view meets with the following difficulties: (1) it is difficult to see in what this process of stabilisation consists, (2) under certain conditions, the heating should lead to an inversion, and not a racemisation. In our opinion, the stereochemical conception of optical activity as a static phenomenon is not entirely satisfactory.

### Measuring the Surface Area of Living Animals

A NEW method of estimating the surface area of living animals used in metabolism work seems likely to be of interest to many biological workers outside the agricultural sphere. Such a method has recently been developed by me in this laboratory.

Although the animals immediately concerned are pigs, the method is applicable generally to all animals not encumbered with a thick shaggy coat, and consists, essentially, in the estimation of the approximate value of the integral  $\int P dx$  over the surface of the animal, where  $P$  is the perimeter in a plane perpendicular to the axis of  $x$ . In the case of pigs, it appeared satisfactory to take  $P = k\pi(a+b)$ , assuming the cross section elliptical for the head and body. Here  $k$  is a constant which indicates the departure from perfect ellipticity and varies somewhat in value at different parts of the body, while  $a$  and  $b$  have their usual connotations in the approximate formula for the perimeter of an ellipse. The approximate integration is then made by Simpson's rule, the values of the ordinates  $a$  and  $b$  for different values of  $x$  being read off directly from scale photographs, one taken from the side and the other from directly above the animal. The ears, legs, and tail are estimated separately.

A consideration of the various corrections required and of the errors involved leads to the conclusion that the total error in the method, when all precautions are taken, amounts to not more than 2.0-2.5 per cent, varying a little with the individual animal, in the case of pigs.

For other animals, the constant  $k$  and the errors would have to be determined, but there seems reason to suppose that—except perhaps in the case of human beings, for whose superficial area a mass of data is available—a very considerable increase in accuracy may be expected by the employment of the method outlined, in preference to the use of empirical formulae depending on weight, height, length, or any or all of these. Experience shows that such formulae are all liable to errors of the order of 10 per cent when applied to animals of the same species other than the ones actually used by the experimenter in determining the formula.

A full account of the method will appear in the April issue of the *Journal of Agricultural Science*.

### Crystal Structure of $\beta$ -Zirconium

FROM the temperature variation of the resistivity, the thermal dilatation and the thermionic emission, C. Zwicker<sup>1</sup> has deduced that zirconium is transformed into another modification between 1150° K. and 1430° K. Quite recently, the transition point was accurately measured by R. Vogel and W. Tonn<sup>2</sup> from a study of the cooling curve. They found it to be  $862^\circ \pm 5^\circ$ . The crystal structure of the high temperature modification ( $\beta$ -zirconium) has been determined by us to be cubic body-centred, with two atoms of the metal in an elementary cube, the side-length of which at a temperature in the neighbourhood of the transition point is 3.61 Å. The experimental details and the high temperature vacuum camera used will be described elsewhere (*Z. anorg. allgem. Chem.*).

## Research Items

**Colombian Archaeology**—An account by Mr J Alden Mason of a year's field work of an expedition of the Field Museum of Natural History, Chicago, to the Santa Marta area of Colombia in 1922-23 (*Pub.* 304, Anthropological Series, vol 20, No 1) describes the examination and excavation of a number of sites in what was once the habitat of the long extinct Tairona Indians. Previously their culture was practically unknown. The area is an island mass rising from tropical coast-land to eternal snow, a system entirely independent of the adjacent Andes. The sites investigated fall into three classes, coastal, foothill, and high mountain. Of the coastal sites, Gairaca provided interesting evidence as to burial customs. It was evidently primarily, if not mainly, an interment site, though it appears to have been occupied seasonally. The interments all date from approximately the same period, and there is no evidence of post-Columbian occupation. The urn burials were secondary—that is, they represent the reinterment of disarticulated bones, but occasionally primary burials were found. Pet animals may have been sacrificed. Implements and ornaments were sometimes enclosed in the burial urns, but more often in smaller urns or in the surrounding soil. Food was also enclosed in small pottery vessels. The pottery is of two types, a coarse red ware with appliqué relief, and thin black polished vessels with incised ornament or moulded relief. The two are evidently contemporaneous. On a site at Nahuange some interesting artefacts were found in association with skeletal remains and pottery vessels. These included six or eight artistic, but highly stylised, heads of crocodiles made of a large univalve mollusc shell, crescentic pendants of shell, tubular beads and other beads of shell, carnelian, etc., two plaques of gold-copper alloy and other gold objects, and ornaments made of univalve shells which may have been used as rattles on clothing. A number of pictographs of a unique character and architectural remains were found at the foothill sites. The material objects found and the scientific deductions will be dealt with in two subsequent reports.

**British Migration Elucidated by Ringing Methods**—H F Witherby and E P Leach have continued their valuable compilation of all the records of birds which, ringed in the British Islands, have been recovered abroad, and of birds which, ringed abroad, have been found in these islands (*Brit Birds*, Dec 1931, p 174). The maps upon which the records of particular species are shown bring out many points in a clear way. The lapwing performs westward and southward movements, British shores being replenished by birds bred in Denmark, Sweden, and Holland, while British native birds have been recovered only south of these islands from northern France, along the west coasts of France, Spain, and Portugal to North Africa. On the other hand, the lists show that mallard and teal which have been bred in the British Isles move east and north, and in their case there is no evidence of a southward migration.

**Habits of a Japanese Limpet**—The limpets (*Acmæa dorsuosa*) of Mutsu Bay show seasonal groupings, the spring to autumn period (April to September) being a season of congregation, when individuals appear in groups above high-water mark, whereas from mid-September to March the groups are dispersed (Noboru Abe *Science Reports, Tôhoku Imp Univ*, vol 4, Sept 1931, p 403). This species has the power of both backward and forward locomotion, and its greatest rate of progress is about 2.8 cm a minute, less than

one-third of the speed attained by its congener *A. schrenckii*. The larger limpets have definite spots to which they return after wandering, but such 'homes' do not appear to be permanent. The force of adhesion of the foot of *A. dorsuosa* is equivalent to 373 gram or more for each square centimetre of the surface of the foot.

**British Palmate Orchids**—H Cary Gilson, in collecting and collating much scattered data referring to the British palmate orchids, has produced a useful summary of information on this highly critical group of plants (*Winchester College Nat Hist Soc Publications*). Descriptions of species and varieties occupy the first part of the paper, and the conflicting opinion on the status of *O. latifolia* are summarised. Hybrid are not described, but many are well illustrated by photographs. The second part of the work deals with the palmate orchids of the Winchester district, together with the author's own views on the constitution of *O. latifolia*, which he suggests may have arisen through the hybrid *O. maculata* (agg.)  $\times$  *protermissa* by repeated back-crossing of the progeny with one parent followed by selfing to give a small proportion of homozygous plants. The suggestion, whilst providing an explanation of some of the observed facts connected with the polymorphism of *O. latifolia*, is quite hypothetical, and emphasises the need for cytological and genetical examination of this and related orchids.

**Geology of East Greenland**—The geological work of the Cambridge Expedition to East Greenland in 1929 has been described in an important paper by M M L Parkinson and W F Whittard (*Quart J Geo Soc*, pp 650-74, 1931), with some excellent maps and illustrations. The work was concentrated mainly on the elucidation of certain tectonic problems in the pre-Old Red Sandstone rocks of the area about the Franz Josef and King Oscar Fjords. The outstanding fact in the Palaeozoic geology of the region is the triple repetition of belts of sedimentary and metamorphic rocks, and its explanation appears to be closely related to the Caledonian movements. In pre-Cambrian times a complete trough of deposition lay north and south between Laurentia and Baltica. In the East Greenland mountains the shallow-water sediments then deposited in the western border of this trough are preserved. In Cambrian times two or more geanticlines of pre-Cambrian metamorphic rocks which had appeared earlier continued to develop, while the intervening basins harboured shallow-water sediments with shelly faunas. Wedges of metamorphic and sedimentary rocks advanced westwards up thrust planes. The main pressure persisted until at least the Middle Ordovician and possibly the Silurian. The Central Metamorphic Complex represents the most westerly of these geanticlines, while the most easterly is the Eastern Metamorphic Complex.

**The South Sandwich Islands**—Little has been added to the knowledge of these subantarctic islands since their discovery by Cook in 1775 and the visit by Bellingshausen in 1820 until *Discovery II* spent some days at the group in 1930. In a lecture to the Royal Geographical Society on Dec 14, Dr S Kemp gave an account of the main discoveries. All the eleven islands are of volcanic formation dating probably from tertiary times. Five still show signs of activity with craters and fumaroles emitting steam and vapour. Three others retain some warmth, and the remainder

three are more or less heavily glaciated. There is considerable evidence of lost land areas around some of the islands. The introduction of echo-sounding into this area of the South Atlantic has thrown light on the relation of the group to other land areas though more work must be done before the problem is finally solved. There is strong evidence of a submarine ridge extending between South America and the South Sandwich group via the Burdwood Bank, the Shag Rocks and South Georgia, but the continuance of the ridge between the South Sandwich Islands and the South Orkneys is not so well established. East of the islands there is an extensive curved deep falling to at least 4421 fathoms. These facts support Suess's theory of the South Antillean arc, which is further supported by the occurrence of typical Andean lavas in Thule Island, the southernmost of the group.

**Mapping of the Southern Ocean**—A chart of the Southern Ocean, from long  $50^{\circ}$  S to  $73^{\circ}$  S and from lat  $20^{\circ}$  W to  $100^{\circ}$  E, has been worked out on Mercator's projection by the Norwegian Geographical Institute, the scale being 1 4,000,000 at  $60^{\circ}$  S (Publikasjon nr 10 fra Kommandør Chr Christensens Hvalfangstmuseum, Utarbeidet for Hvalangernes Assuranceforening, Sandefjord). A considerable number of fresh soundings obtained by Norwegian antarctic whaling expeditions are included. A plan (1 100,000) is given of Bouvet Island, which was the subject of diplomatic exchanges some years ago and was ceded by Great Britain to Norway in 1928 as an act of grace.

**A Sensitive Barograph**—We have received from Messrs Negretti and Zambra, the well-known scientific instrument makers, a specimen record of the variations of atmospheric pressure during the week Jan 18-25, 1932, obtained with the aid of a micro-barograph which gives a record on a scale of five inches to an inch of mercury. This instrument is numbered M 2071 in the firm's catalogue of standard meteorological instruments, and is styled the Precision Recording Barometer. In order to obtain sufficient control to overcome the friction involved in obtaining such magnification, four sets of special diaphragms are used in pairs. Their movement is transmitted to the main lever through flexing strips, thus avoiding the use of pivots, and then by a special form of link to the pen arm, the record being obtained on the ordinary clock-driven drum. The charts are five inches wide, since this does not provide for the possible range of pressure in one place, it is necessary to reset the pen when the latter reaches the top or bottom of the chart, there is a spring-controlled thumb-screw for carrying this out. A failure to secure the necessary freedom of movement for recording minute variations of pressure would be evident from the appearance of 'flats' or 'steps' in the trace. Of these there are no examples on the specimen chart, which incidentally, thanks partly to the quiet anticyclonic conditions prevailing during the week in question, shows the diurnal variations of atmospheric pressure very clearly. One obvious use of the instrument is for obtaining the changes of pressure at the ground for correcting the indications of height given by an altimeter. The claim that it will measure changes of the order of two hundredths of an inch would appear to be an understatement of the sensitivity if the specimen record is a typical one. The price, with ink, pen, and 100 charts, is £40.

**Origin of Vitamin C**—Three Scandinavian workers, Ottar Rygh, Aagot Rygh, and Per Laland, have obtained what appears to be conclusive evidence that

narcotine, one of the less toxic alkaloids present in opium, is a, if not the, precursor of the antiscorbutic vitamin C. In the first issue of the *Zeitschrift für physiologische Chemie* for 1932, these authors describe how they found the alkaloid in various unripe fruits and vegetables, but failed to detect its presence in the ripened materials. From 200 unripe oranges they prepared 600 mgm of the alkaloid, and by extracting the concentrate, consisting of oil and crystals, from 15,000 oranges at various stages of ripeness, they were able to trace the gradual increase in antiscorbutic power as ripening proceeded. Pure, commercial narcotine was not antiscorbutic, but irradiation from a quartz mercury vapour lamp activated it to some extent without appreciably altering its physical properties. Guinea-pigs were fed on dietaries containing narcotine and irradiated narcotine, both groups died about the same time, but the former group developed strong signs of scurvy before dying and the latter none. Narcotine was found in unripe tomatoes (20 mgm in 20 kgm), white cabbage (40 mgm in 100 kgm), and in potatoes (12 mgm in 20 kgm), qualitative indications of the presence of narcotine were found in milk, but none in red bilberries. Of various derivatives of narcotine, the ortho-dihydroxy derivative—methylornarcotine—was found to be particularly antiscorbutic. In presence of germinating seeds, known to produce vitamin C, narcotine became active, it disappeared and gave rise to phenols.

**Electric Moment and Temperature**—Experiments on dipole moments of substances have shown that, in many cases, these are independent of temperature. One or two cases in which a variation has been reported have been explained on the basis of association, but they are somewhat doubtful. Smyth, Dornie, and Wilson have now discussed the effect of intramolecular rotation upon the moment of a molecule of the type of ethylene chloride, both on the classical and quantum theories (*J Amer Chem Soc*, Dec 1931). The quantum calculation shows that, at room temperature, the great majority of the molecules are in low energy levels, where the dipoles oppose one another to a considerable extent, giving a low mean moment. With rising temperature there is an increased oscillation, but the seventy-fifth level is still short of complete rotation. In the experimental part of the paper it is shown that the polarisation of ethylene chloride increases with rising temperature in dilute solutions but decreases in concentrated solutions, the change of polarisation with concentration being surprisingly small. The moments of ethylene chlorobromide and diethyl succinate also vary with temperature. Ethylene chloride and bromide, ethylene chlorobromide and diethyl succinate show different moments in heptane and benzene solutions, so that the moment of a molecule containing two or more dipoles, the axes of which may alter their positions relative to one another, may be affected both by temperature and environment.

**Theory of the Glass Electrode**—Dole has described (*J Amer Chem Soc*, Dec 1931) some experiments on the glass electrode and given a full critical account of the theories proposed to explain the behaviour of this electrode. The electrode behaves differently in three well-defined pH regions. Between pH 1 and pH 9 it gives potentials which vary with the hydrogen ion activity in the same way as a hydrogen electrode. Above pH 8 or 9 and below pH 0 or 1 it behaves anomalously. There are three main groups of theories of its behaviour, namely, the phase boundary theory, the ion exchange or adsorption theory, and the membrane or diffusion potential theory. There are some

difficulties in all these theories in their present state, the first being inconsistent with facts and the second containing improbable or unverified assumptions. A new equation for the electrode is developed which is shown to agree with the data up to  $pH$  12. A similar equation may be derived, for univalent salts, from the Henderson and Planck liquid junction equations if the relative mobility of the positive ions is assumed to be a function of  $pH$ . It is assumed that the electric double layer at the glass-aqueous solution interface determines the selective mobility of the ions across the boundary.

**Anhydrous and Hydrated Manganese Sulphate**—In a paper presented recently to the Czech Academy of Science (*Collection of Czechoslovak Chemical Communications*, 1931, pp 517-35) Prof. H. Křepelka and Dr. B. Rejha describe the results of an exhaustive research upon the hydrates of manganese sulphate. No less than fourteen different compounds have been mentioned in the literature, but in this investigation the authors have established the existence of only six of these, namely, the anhydrous salt, two forms of the monohydrate, and salts with four, five, and seven molecules of water of crystallisation. Those compounds previously described as possessing a half, two, three, and six molecules of water of crystallisation are said definitely not to exist. It is further stated that anhydrous manganese sulphate can be prepared

from any of the hydrated salts by heating first to  $100^\circ C$ , then at  $150^\circ$ , and finally at about  $550^\circ C$  in an electric furnace and, afterwards, slowly cooling in a desiccator. Much attention was paid in this research to the monohydrate,  $MnSO_4 \cdot H_2O$ , which is readily prepared by heating any of the higher hydrates above  $100^\circ C$  but below  $200^\circ C$ . The authors found that it was unnecessary to specify definitely any exact temperature between these limits. Again, on exposure to air the higher hydrates effloresce, leaving the monohydrate, which, it is concluded, must have the same pressure of aqueous vapour as the atmosphere. The anhydrous salt also absorbed moisture from the air, forming the monohydrate. Prepared in this manner the salt is not polymerised, but when formed by dehydration at temperatures above  $100^\circ C$ , its molecular weight was double that of the single salt. The essential condition for the separation from solution of crystals containing four molecules of water of crystallisation is that the temperature should be between the limits  $26^\circ$  and  $45^\circ C$ . Above and below these points mixed crystals make their appearance, and this may have misled earlier investigators into the error of reporting the isolation of non-existent hydrates. The salt,  $MnSO_4 \cdot 5H_2O$ , separates most conveniently from aqueous solution between  $9^\circ$  and  $26^\circ C$ . Below  $9^\circ C$  ordinary manganese sulphate with seven molecules of water of crystallisation is deposited.

### Astronomical Topics

**Sunspot Activity during 1931**—In the annual report of the Council to the Royal Astronomical Society, a summary is included of the sunspot activity for 1931. The average daily area of sunspots measured at Greenwich was approximately 260 millionths of the sun's hemisphere. This value for 1931 is half that for 1930, and the average daily number of spots showed a decrease in about the same ratio. On about forty days during 1931 no spots were seen on the sun's disc. Large groups of spots were, however, by no means entirely absent, and the following dates are the times of central meridian passage of groups of spots of 500 millionths or larger, that is, of the order of size at which a spot is visible near the centre of the disc without telescopic aid: Jan 12.5, Feb 20.6, Feb 20.7, March 15.4, May 20.5, Nov 26.9. The largest of these groups, with central meridian passage on Feb 20.7 and in latitude  $6^\circ$  north, had a maximum area of nearly 1900 millionths. A note on this group was given in *NATURE*, 127, 321, 1931.

Thirteen spots, including three of the above, were observed spectroscopically to be more than usually active. This activity often took the form of brilliant, short-lived eruptions of hydrogen ( $H\alpha$ ), which in several cases were accompanied by dark hydrogen markings moving with high velocity of the order of 50 km/sec. Terrestrial magnetic activity was distinctly less than in 1930, there being seven disturbances of storm range registered at the Greenwich magnetic station as compared with twenty-three in the previous year.

The relation of the sun's activity during 1931 to the present eleven-year sunspot cycle is shown by the following values of the mean daily area of sunspots, corrected for foreshortening and expressed in millionths of the sun's hemisphere:

| Year | Area | Year | Area |
|------|------|------|------|
| 1923 | 55   | 1928 | 1390 |
| 1924 | 276  | 1929 | 1242 |
| 1925 | 830  | 1930 | 516  |
| 1926 | 1262 | 1931 | 260  |
| 1927 | 1058 |      |      |

**Two Very Distant Spiral Nebulae**—Science Service Bulletin for Jan. 14 reports a further advance in the study of the radial motion of the distant spirals which has been in progress at Mt. Wilson for some time. Dr. Edwin P. Hubble discovered a cluster of very faint spirals in Gemini, Mr. Milton L. Humason has investigated their radial velocity, and finds a recession of 15,000 miles per second, which is much the highest value yet found. It is generally agreed that the shift of the spectral lines to the red, which is observed in the spectra of these nebulae, is a good measure of their distance from us, whether it arises from actual recession or from some other cause. The distance deduced in the present case is 135 million light-years, which is approaching close to the 150 million light-years estimated some years ago to be the limit of the region of space within the reach of the 100-inch reflector at Mt. Wilson. It is anticipated that the contemplated 200-inch mirror will greatly extend the limit.

**Mass of Eros**—Prof. W. H. Pickering points out in *Popular Astronomy* for January that if we accept the duplicity of Eros, which has long been suspected, and was strongly supported by the observations of Messrs. van den Bos and Finsen at Johannesburg a year ago and those of Mr. L. Campbell at the same time, we have the means of deducing the mass with considerable accuracy. The distance between the centres of the two bodies is taken as 17 miles. Their period of revolution is known with great accuracy from the light-variation, it is  $5^h 16^m 12.94^s$ , the mass comes out  $1/177,000,000$  of the earth, or about  $1/2,000,000$  of the moon. Taking the diameter of each component as 8 miles, Prof. Pickering finds the density of each component to be 15.6 times that of water—an improbably high figure. It would be reduced to the density of iron if the diameters were 10 miles. The latter value for the diameters gives the albedo as 0.30, or two-thirds that of the earth—not an impossible value.

## The University of Edinburgh

## EXTENSION OF DEPARTMENTS OF GEOLOGY AND ENGINEERING

## GRANT INSTITUTE OF GEOLOGY

THE accommodation provided for the teaching of geology at the University of Edinburgh has been very inadequate ever since the establishment of the chair in 1871, with Archibald Geikie as the first professor. Owing to the great influx of students at the close of the War, the Department became so congested that it was impossible to carry on the practical classes at the Old University Building.

dors are returned down the centre of the wings, terminating in a lecture hall, 42 ft. 6 in. by 31 ft. (to seat 175), in the east wing, and in a room for the collections of mineralogy and petrology in the west wing. Leading directly from the corridor on the ground floor are the laboratories for economic geology, mineralogy, and elementary and honours petrology, with rooms for the lecturers and for research—and all having windows looking north. On the south side of the corridor are the chemical laboratory, with

FIG. 1.—The Grant Institute of Geology, Edinburgh.

Temporary quarters were provided in wooden huts which served the purpose for a time, but by 1929 these were falling into a state of disrepair. At this juncture, Sir Alexander Grant came to the aid of the University, and gave £50,000 for the erection of a new geological building. Sketch plans were prepared by Prof. Jehu and his staff and placed in the hands of the well-known architects, Sir Robert Lorimer and Mr. John F. Matthew.

The new building was completed this year and was formally opened by the Prime Minister on Jan. 28. It forms a part of the King's Buildings inaugurated by King George V., and is situated midway between the Chemistry and Zoology Departments, with a frontage of 213 ft. The building has two wings, giving a total depth from north to south of 108 ft.

The main entrance, facing north and centrally placed, leads to the hall and staircase, with corridors branching off right and left the whole length of the building, and lit by windows at the ends. The corri-

balance room, and photographic and optical dark rooms, a workroom, and cloakrooms for men students. The accommodation in the wings includes a large blow-pipe laboratory with students' and departmental rock-cutting rooms, research, tutorial, and preparation rooms.

On the first floor facing north are the professor's room and laboratory, laboratories for elementary and advanced palaeontology, a room for the lecturer in palaeontology, and a group of research rooms. On the south side of the corridor are the assistant's room, the office and typist's room, cloakroom for women students, and storage accommodation. In the west wing lie the room for stratigraphy and map drawing, a small lecture room, with the library occupying the south end. The library is perhaps the best-equipped departmental library in the University, due largely to the gift of books and papers by the two Geikies. The east wing is occupied by the elementary palaeontology laboratory, and a research room, and terminates

in a large museum. The museum contains mineral collections given by Mr. Brown of Lanfine; the collection of minerals, rocks, and fossils left by Sir Charles Lyell and presented by the late Lady Lyell of Kinnordy; and the collection of the late Dr. James Currie, so generously given to the University by Mrs. Currie and family.

In addition to the main staircase, a service stair has been provided in each wing, and an electric lift. Both the library and the museum have storage rooms adjoining, and in the attic a large space has been reserved for the accommodation of surplus collections.

enlarged fossil shell forms the setting for the figure. This feature is the work of Alexander Carrick.

The University is now provided with an excellently planned and well-lit building worthy of the city of Edinburgh.

#### SANDERSON ENGINEERING LABORATORIES

The new engineering building also forms part of King's Buildings. It fronts Mayfield Road and lies south of the new zoology buildings. In plan the front extends to a length of 200 ft. with a depth of 144 ft. from east to west, the water tower and cement and

FIG. 2.—The Sanderson Engineering Laboratories, Edinburgh.

At the east end of the building, owing to the level of the ground, an excellent basement was made possible, and here are situated the heating chamber, switch room, additional storerooms, and access to the lift.

The masonry of the new building is of sandstone from Blaxter Quarry in Northumberland. The floors are constructed in reinforced concrete, and the roofs are covered with Ballachulish slates. The window frames are galvanised steel. The heating is by low pressure steam supplied from the central boiler installation, which supplies the heating for all the buildings on this site. The paving in the entrance hall and the staircase is synthetic stone. The floors and dadoes in the corridors and cloakrooms are finished with terrazzo, otherwise the flooring throughout is pitch pine.

Appropriate to the purpose of the building, the figure carved in stone over the main entrance represents early man seated on a rock, his left arm supporting a slab with a fossil shell embedded in it; another

concrete testing rooms projecting beyond the west side. The two-storied front part of the building accounts for practically one half of the total area. On the ground floor are a lecture hall, with seating accommodation for 216 students, and three smaller classrooms, lavatories, and various storerooms. The front upper floor is devoted to the drawing office—a spacious room 155 ft. long and 28 ft. wide—and the departmental library, while on the west side of the upper corridor are the various staff rooms and rooms for photographic work and research.

A corridor on the ground floor, 12 ft. wide, extending the whole length of the building, gives access from the front of the building to the four laboratories, workshop, and boilerhouse; these are all one story in height, well lit by roof lights in the steel-constructed roof. Wide sliding doors at the rear of the laboratories give access to the roadway surrounding the building, and this facilitates the reception of new machinery or plant for testing purposes.

The most southerly of the laboratories, devoted to experimental work on the testing of materials, has a floor area of about 3000 square feet, and is equipped with some twenty testing-machines, varying in power from 1 ton to 100 tons. The plant is arranged both for ordinary teaching work and for research.

Adjoining this are the heat engines laboratory, divided into two bays, and the boilerhouse—the floor space is about 5000 sq. ft.; one bay is devoted to internal combustion engines and the other to steam plant. The plant in the internal combustion bay includes types of gas engines and heavy and light oil engines of the most recent make, and in the

hydraulics laboratory, the floor of which is laid out on two levels. Most of the experimental apparatus is on the upper level, and all the discharge from this apparatus is led by drainage channels to large measuring tanks beneath the floor at the lower end of the laboratory. An open concrete channel, 30 ft. long and 3 ft. wide, runs the whole length of the upper level and discharges over a weir into the measuring tanks, which have a capacity of 10,000 gallons. The tanks have been built in reinforced concrete. For work requiring a steady head, a storage tank of 6500 gallons capacity has been built in, at the top of the water tower, giving a head of 70 ft. Every

FIG. 3.—Heat Engines Laboratory in the Sanderson Laboratories.

steam bay both reciprocating engines and turbines have been installed. All the necessary condenser plant for these is concentrated in a pit some four feet below the laboratory floor level. All these units are fitted with measuring appliances to enable complete thermal efficiency tests to be made. The experimental steam boiler, of the latest Yarrow type, can supply ample steam at a pressure of 250 lb. either saturated or superheated, and the boiler is equipped with all the necessary measuring appliances for complete thermal tests under all working conditions.

The next bay to the north is occupied by the

piece of apparatus in this laboratory is provided with a measuring gauge, either of the Venturi type or of the orifice type, thus making it a self-contained unit, so that many experiments can be carried on simultaneously.

Beyond the hydraulics laboratory, in the last bay, a mechanics laboratory has been fitted up for experimental work on applied mechanics.

The cost of the buildings was met by a bequest of about £50,000 by the late Mr. James Sanderson, senior partner in the firm of Messrs. R. and A. Sanderson and Co., one of the oldest established firms in the Scottish tweed trade in Galashiels.

### Mental Deficiency

**D**URING the centenary meeting of the British Association held in London in September, several papers on different aspects of mental deficiency were read before Section J (Psychology). Dr. E. O. Lewis spoke on the social aspect of the subject, Prof. F. A. E. Crew on its genetic background, Dr.

F. C. Shrubbsall on the incidence of different types, and Dr. R. G. Gordon on some psychological experiments he made on mental defectives at Stoke Park Colony in collaboration with Dr. E. Norman.

Dr. Lewis set forth some fundamental issues involved in the social problem. Public interest has

been shown in mental deficiency and especially in the discussion of remedial measures. Some of these measures bear the hall-mark of empiricism; they show no clear conception of the nature of mental deficiency and would, if adopted, probably do much harm without achieving much good. Progress in arriving at a solution of the social problem presented by mental deficiency is considerably hampered by failure to appreciate the complexity and variety of clinical conditions to which the generic term 'mental deficiency' is applied. There are varying degrees and varying types, so that it is advisable to speak of mental deficiencies rather than mental deficiency. No single remedial measure is applicable to all cases.

Mental deficiency is a variation from the normal, and there are two types of such variation, normal and abnormal: the former is called by Dr. Lewis *sub-cultural*, the latter *pathological*. The pathological group comprises those whose condition is due to a definite organic lesion or abnormality; in the sub-cultural group there is no such alien factor, the deficiency is only an extreme variety of normal variation and of mental endowment; there is no definite cleavage between this group and the mass of normal persons. The higher grades of sub-cultural deficiency merge gradually into the lower grades of dullness or of temperamental instability; there is a close biological kinship between them and the mass of normal persons, a kinship which can not be attributed to the pathological defective.

This classification, Dr. Lewis considers, helps one to understand the social problem. Most of the pathological cases are lower grade defectives, idiots or imbeciles, whereas most of the sub-cultural cases are feeble-minded, a milder form of mental defect. Most defectives belong to the sub-cultural group: the feeble-minded are approximately three times as numerous as the lower grade defectives. The pathological cases are evenly distributed among all sections of the community, whereas the sub-cultural type is concentrated to a large extent in the lower section and is often associated with various chronic social evils, such as chronic pauperism, slumdom, and its concomitants. Heredity is an important factor in the production of the sub-cultural group, though, undoubtedly, pathological defects also are inherited in some cases. When several defectives appear in one family, they are almost invariably of the sub-cultural type, and most of the members of the family who are not mentally defective are of subnormal intelligence.

It is the sub-cultural group which is the social problem. The fact that it is a normal variant makes it an index of the mental state of the whole group—it is a form of general mental debility. Remedies should not be surgical, but preventive: the solution of the social problem of sub-cultural mental deficiency lies in increasing the mental vitality of the whole community.

Prof. Crew, speaking on the genetic background of mental defect, said the human subject is the least convenient material for genetical study, that almost all that is known of hereditary characters refers to details of structure which are easily recognised and readily measured, and, save by grossly unfavourable physical conditions, are apparently uninfluenced by environmental factors, but that there are many heritable characters the actual expression of which is conditioned by environmental agencies. There are three kinds of mental deficiency: (1) the type in which the character is the direct expression of genetic factors unaffected in their action by environmental forces; (2) the type in which the character for its expression requires the interaction of genetic con-

stitution and environmental factors; and (3) the type which is a non-inherited acquisition. Differential diagnosis is difficult: the real difficulty is to decide whether genetic or environmental factors (or both) are operating in any given case. The difference between normality and abnormality may be magnified by environmental agencies. So long as the demonstrable significance of those agencies is disregarded and attempts are made to find a single constant basis for a character which can be the end-result of so many different developmental happenings, there can be no hope of assessing the rôles of whatever genetic factors may enter into the determination of mental deficiency.

Since defect of mind is no more of a biological unity than is defect of body, mental deficiency may be genetically many different things, in some instances an autosomal recessive, in others an autosomal dominant, sex-linked, or multiple factor character, or even a step-allelomorph. The evidence points in that direction, and such a view is more helpful in an analysis of the etiology of the condition than that which insists that there is a constant genetic origin for it. That genetic factors play a prominent part in the etiology of mental deficiency is certain, but as to their nature or number there is no precise knowledge. What is needed is investigation and careful critical analysis. Only when such research has been carried out can policies relating to the control of mental deficiency through controlled breeding be framed which will command the unqualified endorsement of the geneticist.

Dr. R. G. Gordon described the results of a repetition on two hundred mental defectives of experiments made by Sir Henry Head on aphasics. He found that while language as a whole is difficult for defectives, pure language manipulation is easier than spatial orientation and control, and that this conclusion is borne out by other experiments with puzzle-boxes in which the behaviour of his subjects showed definite similarity to that obtained by analogous experiments with animals.

### University and Educational Intelligence

CAMBRIDGE.—The Gordon Wigan prize for chemistry for 1931 has been awarded to A. H. Hughes (Trinity Hall) for a thesis entitled "The Constitution of Surface Films of Organic Molecules".

The Cambridge University Natural Science Club will hold a dinner on Saturday, March 5, to celebrate the 1300th meeting of the Club. Past members wishing to attend should communicate with the secretary, D. W. I. Piggott, Gonville and Caius College, Cambridge.

GLASGOW.—The Frazer lecture in anthropology will be delivered on March 4, by Sir Arthur Keith.

THE annual meeting of the Association of Technical Institutions will be held in the Leathersellers' Hall, St. Helen's Place, London, E.C., on Feb. 26-27, under the presidency of Sir John Dewrance. The following papers will be read: "Technical Education in Canada", by Prof. R. W. Angus; "Technical Education in the Bakery Trade", by Mr. W. H. Quinn; and "Teaching of Modern Languages in Technical Colleges", by Mr. P. G. Wilson. Mr. J. Cameron Smail, principal of the Heriot-Watt College, Edinburgh, will give an address on the report on "Policy in Technical Education", and Sir Francis Goodenough on the report on "Education for Salesmanship". A demonstration of the use of the gramophone in

teaching modern languages will be given by Mr W. H. Kerridge. The secretary of the Association is Dr. H. Schofield, Loughborough College, Loughborough, Leicestershire.

THE examination for county minor scholarships of 15,485 children of 10-12 years of age in the West Riding of Yorkshire last February forms the subject of an interesting report issued by the County Education Committee. The task of organising the assignment of marks to so large a number of examinees with the nearest possible approach to uniformity presents formidable difficulties, and the report sets out in detail how these difficulties were met. A decentralised system of marking was adopted in 1927 with the object of associating in the conduct of the examination the whole body of teachers in the area. By selecting the assistant examiners from a panel nominated by local committees, by limiting their number to about fifty, by assigning to them scripts in their favourite subjects, and by facilitating conference and consultation, this system has gradually been perfected and is now working satisfactorily. For the written test, papers were set in English and in arithmetic. These are reproduced in the report, with comments by the chief examiners. Taken with the statistics of results classified according to percentages of marks obtained, the whole report gives a fairly definite measurement of the intelligence of the children of the county.

### Calendar of Geographical Exploration

Feb. 22, 1878 —The Essequibo and its Tributaries

Sir Everard im Thurn started from Aretaka, south of Bartica, on his first expedition up the Essequibo River. Thence he went by canoe to Pirara, and from that point crossed the savannah to the Takootoo River, down which he travelled to its junction with the Branco. Later in the same year he visited the Kaieteur falls on the Potaro River, which here leaps 750 feet, the falls had been first visited in 1871 by C. Barrington Brown. In further visits to the region he explored other rivers, notably the Cuyuni and the Mazaruni. But his most important work was on the ethnological side, his studies of the customs of the Indians of British Guiana have become a classic.

Feb. 23, 1540.—The Coronado Expedition

F. V. de Coronado left Compostela with an army to conquer the Seven Cities of Cibola, now identified as probably the Zuñi Pueblos of New Mexico. Coronado went to Mexico in 1535 and became governor of New Galicia in 1539. In that year he heard rumours of the fabled wealth of Cibola and determined to conquer it. In this he succeeded, but he found no wealth. He moved westwards to the Rio Grande and sent out exploring parties, one of which found the records of Alarcon. The latter in 1540 ascended the Gulf of California and explored the Colorado River from its mouth. He reported that lower California was a peninsula. Another party under Cardenas discovered the Grand Cañon of the Colorado, which baffled their efforts to cross it. Coronado himself proceeded to Quivira, reported to be an El Dorado, which seems to have been in the region where the Arkansas and Kansas Rivers approach one another. Coronado and the tattered remnants of his army reached Mexico in 1542, having completely failed to find gold or silver. But from a geographical point of view his march was of first-class importance. It formed the basis of the cartography of the hitherto unknown interior of the northern continent. It gained the first information about the sedentary Pueblo tribes of the south-west

of the United States and about the hunting tribes of Indians dependent upon the bison, an animal never before seen by the Spaniards, who called it a cow. In addition, the Grand Cañon had been discovered and the lower Colorado explored.

Feb. 23, 1770 —The Great Slave Lake

Samuel Hearne, an agent of the Hudson Bay Company, started on a journey the objects of which were to verify a rumour of the existence of copper ore and to find out whether there was a passage westward from Hudson Bay. He reached the northern shore of Dubawnt Lake, but there broke his quadrant and therefore returned. He had covered some new ground, but had failed in the main object of his journey. In December of the same year he started again, reached the Coppermine River, and followed it to its mouth, thus for the first time reaching the Arctic Ocean in this region. On his return journey he followed a different route and discovered the Great Slave Lake, which he crossed. He himself called the lake Athapuscow, and it was by some thought to be Athabasca, but his route indicates that this was a mistaken identification. His voyage settled the question of the existence of a north-west passage from Hudson Bay.

Feb. 26, 1807 —Pike's Peak

Z. N. Pike arrived at the Rio Grande del Norte, in the region where Alamosa, Col., now stands, and was taken prisoner by the Spanish authorities. Pike had set out in 1806 to lead an expedition which was to explore the country west and south-west of St. Louis to the headwaters of the Arkansas and Red rivers. He ascended the Arkansas through the Royal Gorge and sighted the mountain which now bears his name. He mistook the Rio Grande del Norte for the Red River. The Spanish sent him to Santa Fé and then to Chihuahua, whence he was deported, returning home through Texas. His account of his experiences made available for the first time a fairly accurate knowledge of New Mexico, Texas, and northern Mexico.

### Societies and Academies

#### LONDON

Royal Society, Feb. 11 —J. Chadwick and J. E. R. Constable. Artificial disintegration by  $\alpha$ -particles (2) Fluorine and aluminium. The protons liberated from fluorine and from aluminium when bombarded by  $\alpha$ -particles from polonium have been examined. In each case they can be resolved into definite groups which occur in pairs. The results are explained on the assumption that the  $\alpha$ -particles can enter the nucleus through certain resonance levels. To explain the fluorine disintegration it is necessary to suppose that there are two (possibly three) levels, while for aluminium four levels must be assumed. — A. J. Bradley and A. H. Jay. The formation of superlattices in alloys of iron and aluminium. Alloy structures of iron and aluminium in the range Fe-FeAl are primarily based on a simple body-centred cubic lattice like that of  $\alpha$ -iron, but a detailed examination of the annealed and quenched states gave widely-differing results. Alloys quenched from 600° C. and above showed a random distribution of atoms up to 25 atomic per cent aluminium. Between 25-26 per cent and 50 per cent aluminium, cube centres differ in composition from cube corners. Annealed alloys with less than 18 atomic per cent aluminium have a random distribution, and at 40-50 per cent aluminium they have the FeAl type of structure exactly like the quenched alloys in this range. At intermediate compositions a new type of structure appears, which

is of the type  $\text{Fe}_3\text{Al}$ . In the latter the aluminum atoms lie on a face-centred cubic lattice with dimensions twice as great as those of the small body-centred cube—E B Moullin. A method of measuring the effective resistance of a condenser and of a long, straight wire. The method consists in using similar coils with wires of different specific resistance, and in plotting the measured resistance of the whole circuit against the calculated resistance of the coil. The result is a straight line which does not pass through the origin, thus showing that there is a component of resistance which does not depend on the conductivity of the material: the intercept on the resistance axis shows the effective resistance of the condenser at the frequency in use. The coils were long, narrow rectangles, and for such the skin effect formula for a long, straight wire is applicable without modification.

## DUBLIN

Royal Dublin Society, Dec 15—J Lyons and W. Finlay. The accuracy of fat determinations in butter-milk, and the effect of the presence of lecithin. The quantity of fat in buttermilk, as determined by certain methods, is affected by the lecithin content. The Gerber test is compared with the Rose-Gottheb and the Minnesota tests, and the results show that the Gerber, like the Rose-Gottheb, is affected by the lecithin present, while the Minnesota is not influenced by it.—J. H. J. Poole. Some measurements of the rate of flow of heat from water at nearly  $0^\circ\text{C}$  to a submerged horizontal ice surface. The problem of the transference of heat from a liquid to its own solid by convection currents is of some geological interest. This paper describes certain measurements made for water and ice. The heat flow obtained was rather larger than had been expected. Unfortunately, however, it is difficult to determine what effect the dimensions of the ice surface would have on the results.

## PARIS

Academy of Sciences, Jan 4—L Blaringhem. The fertility of the white lily, *Lilium candidum*. Details of a method of obtaining good seeds.—Gabriel Bertrand and P de Berredo Carneiro. The existence and distribution of caffeine and of theobromine in the organs of the guarana. Both caffeine and theobromine were found, but very unequally distributed in the various organs.—Emm de Margerie. Third and last report on the publication of the geological works of Marcel Bertrand.—Lucien Daniel. *Procydonia Claraci*.—Bertrand Gambier. The transformation of a simply infinite family of geodesics and of the family of conjugated curves.—Paul Delens. Varieties with affine connexion. The generalisation of Riccati's equation.—Gaston Julia. A decomposition of multiply connex areas.—Paul Montel. Harmonic functions admitting exceptional values.—René de Possel. Some problems of conformal representation.—Arnaud Denjoy. Some points of the theory of functions.—Paul Le Rolland. On the possibility of realising an arrangement for the measurement of time, insensible to the accelerations of its support.—F. J. Bourrières. The free oscillations of the extremities of elastic tubes traversed by a uniform current of fluid.—H Journaud. Vortices in bands.—D. Rosenthal. The increase of resistance to repeated impacts of parts joined by welding.—Pierre Dive. The existence of a permanent regime of rotation in a fluid star with rings.—Henri Mineur and Pierre Guintini. The analytical study of the movements of the helium stars.—Georges Bouligand. A point concerning the technique of vibrations.—R. Ferrier. The slip of a periodic electrical influx along a cylinder axis.—A. Guillet. Contribution to the construction and use of

an apparatus for the measurement of small deformations.—Th V. Ionescu and C Mihul. Ionised gases in the magnetic field. Proof of the existence of the spinning electron. An experimental study of the effect of a magnetic field, parallel to the armatures of the ionised gas condenser, on the variation of the capacity and conductivity of this condenser for wavelengths between 2.34 metres and 19 metres. The experimental curves coincide well with the calculated curves.—J J. Trillat and Th v Hirsch. Researches on the diffraction of electrons by single crystals of gold and platinum.—C. Cheneveau and C Courty. The direct measurement of the magnetic susceptibilities of liquids by the Curie-Cheneveau magnetic balance. With a calibrated tube of the ordinary pattern, it is possible to measure directly the magnetic susceptibility of a liquid with the Curie-Cheneveau magnetic balance without weighings and without determining the density of the liquid.—P Lambert and J Lecomte. The infra-red absorption spectra of the benzene hydrocarbons.—J. Cabannes and A Rousset. The rules of polarisation of the Raman lines in liquids. Theoretical statements and experimental verifications.—René Audubert. The influence of electrolytes on photovoltaic phenomena. Admitting the photolysis of water, suggested as a working hypothesis by the author in a previous paper, a rational explanation is afforded of the influence of electrolytes on the photovoltaic effects.—A Grumbach and F. Taboury. The law of equidistances in photovoltaic batteries.—P. Fourmarier. The study of the lag in photoelectric gas cells. In the working of gas cells the ionisation by the positive ions cannot be neglected: this ionisation is probably the main cause of the lag.—K Boratynski and A Nowakowski. Researches by means of X-rays on the modifications of phosphoric anhydride. From the X-ray photographs it is concluded that commercial phosphorus pentoxide consists mainly of a crystalline form. During sublimation there is a partial disappearance of the crystalline structure and this is attributed to a process of polymerisation.—Georges Denigès. The direct realisation of the permanganate reaction of manganese even in solutions containing as much chloride as sea water. The usual methods for converting manganese salts into permanganate (lead peroxide, sodium bismuthate) fail in the presence of chlorides. Oxidation with hypochlorite, in the presence of copper sulphate as catalyst, can be carried out in presence of chlorides.—G Champetier and U. V Thuau. The dehydration of cupric hydroxide. X-ray diagrams of cupric hydroxide, taken at various stages of dehydration, show that at no stage are compounds other than copper oxide and copper hydroxide present.—A. Perret and R Perrot. Lithium cyanamide. Study of the reaction between lithium and cyanogen.—Mme Ramart-Lucas and J Hoch. The absorption in the ultraviolet and chemical reactivity of certain classes of organic compounds.—Charles Dufraisse and Nicolas Drisch. Researches on the dissociable organic oxides. Substances presenting reversible oxidisability in aqueous solution. Dibromorubrene has been converted into the corresponding dicarboxylic acid by the Grignard reaction. The solutions of the free acid and its salts present all the peculiarities characterising solutions of bodies belonging to the rubrene group, including the decoloration by air in the presence of light, and the formation of a dissociable oxide.—L. Palfray, S Sabetay, and Mlle. Denise Sontag. The action of potash on some aryl-fatty mercaptans. The primary mercaptans, in the  $\beta$  position with respect to the phenyl residue, lose sulphuretted hydrogen much more easily to potash than the other aryl-fatty mercaptans.—Charpentier and

Bocquet Crystallised sodium  $\alpha$ -glycero-phosphate — R Cornubert and P Robinet Constitution of the combinations known as tetrahydropyronic — Paul Gaubert The crystals produced by the solidification of a fused substance containing colouring matters in solution — Jean Lacoste Observations on the pre-Riffian and southern Riffian nummulitic series — Paul Fallot. The geology of the borders of the provinces of Murcia and of Alicante — P Russo The age of the formations of the Zuma basin, region of Safi (Morocco) — D. Skobeltzyn The angular distribution of the ultra-penetrating rays (cosmic rays) — M. Branas The caryology of the Ampelideae — Joseph Szymanek and Pierre Gavaudan Caryological observations on some species of *Gossypium* — N. Löwenthal. The transformations of orthogenetic order of the external Merbomus glands in some rodents — Paul Remy. The fauna of forest humus. — René Hazard Spar-teine and adrenaline — Mme. J. Goude-Axelos and André Claude. Bulbs with rare gases for the production of ultra-violet radiations. Tubes containing mixtures of neon, xenon, and krypton, excited by high-frequency currents with external electrodes, were studied from the point of view of use in therapeutics and also for use as daylight lamps for colour matching. Variations were made in the proportions of the gases in the tube and in the density of the current — A Paillet The variations in normal bacterial parasitism in *Chaetophorus lyropictus* — Georges Lakhovsky. A new method of filtration and sterilisation permitting the production of a bactericidal water. By the introduction of a certain proportion of silver chloride into the paste used for the preparation of porous porcelain filters, a filter tube is obtained containing finely divided metallic silver. Water filtered through such a tube is sterile.

## WASHINGTON, D C

National Academy of Sciences (*Proc*, Vol 17, No. 10, Oct. 15, 1931). — O. Veblen and J. H. C. Whitehead A set of axioms for differential geometry Describing the class of manifolds of  $n$  dimensions to which the theories at present grouped under differential geometry are applicable — H. Bateman Solutions of a certain partial differential equation — W. J. Trjitzinsky. A synthesis of the theorems of Hadamard and Hurwitz on composition of singularities — Wilder D. Bancroft and J. E. Rutzler, Jr. Reversible coagulation in living tissue (6) Histamine can poison the central nervous system, producing anaesthesia as well as affecting the sympathetic system. Experiments on fresh nerve tissue suggest that the effect is due to reversible coagulation of proteins in the tissue. — (7) The tetanic convulsions caused by strychnine can be checked by sodium rhodanate (peptisation), ephedrine (peptisation), chloroform (agglomeration), curare (motor nerve coagulant) and potassium salts (muscle coagulant). The effects can be explained on Claude Bernard's theory of reversible coagulation of proteins — Arthur Bramley: Radioactive disintegration A theoretical discussion — Francis G. Benedict and Edward L. Fox: Body temperature and heat regulation of large snakes In the python the mouth and rectal temperatures are the same; in the fasting boa rectal temperature is lower than temperature of environment and follows slowly rises and falls with the latter During muscular activity, digestion, and incubation rectal temperature is above that of the environment. Calorimetric measurements showed that in repose the snake gave off no sensible heat, all the heat resulting from metabolism being lost through vaporisation of water By the use of a respiration chamber it was shown that a large snake loses 4.5 gm water per kgm body weight per 24 hours at 30° C

No. 3251, Vol. 129]

## Forthcoming Events

## Societies

## FRIDAY, FEBRUARY 19

- INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting) (at Hotel Victoria, Northumberland Avenue), at 12 noon — W. A. S. Calder Control of Industry (Presidential Address) — At 2.15 — Dr. Ezer Griffiths. Thermal Insulation
- ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 — Prof. W. E. Le Gros Clark The Structure and Connexions of the Optic Thalamus (2)
- INSTITUTION OF MECHANICAL ENGINEERS (Annual General Meeting), at 5.30 — Report of Council for 1931 — R. W. Bailey and A. M. Roberts Testing of Materials for Service in High Temperature Steam Plant
- ROYAL SOCIETY OF MEDICINE (Radiology Section), at 8.30. — Discussion on X-Ray Treatment of Non-malignant Conditions.
- ROYAL INSTITUTION OF GREAT BRITAIN, at 9 — Prof. C. F. Jenkin The Mechanics of Shifting Sands

## MONDAY, FEBRUARY 22

- ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 — Prof. A. J. E. Cave The Morphological and Functional Anatomy of the Human Cervical Spine

## TUESDAY, FEBRUARY 23

- ROYAL SOCIETY OF ARTS (Dominions and Colonies Meeting), at 4.30 — W. G. Freeman The Empire Fruit Industry (Lecture)
- ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5 — Discussion on Respiratory Movements in Disease
- ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 — Prof. C. Okell The Role of the Haemolytic Streptococci in Infective Disease (Milroy Lectures) (2)
- ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15 — Sir William Bragg Recent Work on Crystal Analysis (3)

## WEDNESDAY, FEBRUARY 24

- ROYAL SOCIETY OF MEDICINE (Comparative Medicine Section), at 5 — Discussion on Milk Fever or Hypocalcaemia in Parturient Cows and Similar Conditions in Other Animals and Man.
- ROYAL SOCIETY OF ARTS, at 8 — Dr. Alexander Scott The Romance of Museum Restoration (Lecture)

## THURSDAY, FEBRUARY 25

- ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 — Prof. C. Okell The Role of the Haemolytic Streptococci in Infective Disease (Milroy Lectures) (3)
- ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15 — Prof. J. B. S. Haldane Heredity in Man (2)
- LIVERPOOL BIOLOGICAL SOCIETY (in Department of Zoology, Liverpool University), at 7.30 — Prof. J. H. Orton. Studies on the Relation between Organism and Environment (Presidential Address)
- HUNTERIAN SOCIETY OF LONDON (at Apothecaries' Hall, Water Lane, E.C.), at 9 — Dr. J. B. Christopherson The Etiology of Chronic Bronchitis (Annual Oration).

## FRIDAY, FEBRUARY 26

- ASSOCIATION OF ECONOMIC BIOLOGISTS (Annual General Meeting) (in Botany Lecture Theatre, Imperial College of Science and Technology), at 2.30 — At 3 — Dr. H. Tattersfield, F. R. Cann, and others Discussion on Laboratory Tests of Insecticides — At 5.30 — Presidential Address Temperature and Humidity in Relation to Insect Control
- ROYAL ASTRONOMICAL SOCIETY (Geophysical Meeting), at 4.30 — Dr. S. F. Grace A Method for the Determination of the Tides of a Broad, Deep Sea, with Application to the Gulf of Mexico — Dr. H. Jeffreys (a) On the Stresses in the Earth's Crust required to support Surface Inequalities, (b) The Deformation of the Earth due to Asymmetrical Cooling
- ROYAL INSTITUTION OF GREAT BRITAIN, at 9 — Prof. C. G. Darwin The Uncertainty Principle in Modern Physics.

## SATURDAY, FEBRUARY 27

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Lord Rutherford of Nelson Discovery and Properties of the Electron (1)

## Public Lectures

## FRIDAY, FEBRUARY 19

UNIVERSITY COLLEGE, at 5 30—Sir E Denison Ross The Unification of Asia under the Mongols  
ROYAL VETERINARY COLLEGE, at 5 30—T M Doyle Diseases of Birds due to Filterable Viruses (1)

## SATURDAY, FEBRUARY 20

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College for Women), at 3—Discussion of Members' Topics  
HORNIMAN MUSEUM (Forest Hill), at 3 30—H N Milligan Nature Studies on the Sussex Coast

## MONDAY, FEBRUARY 22

GUY'S HOSPITAL (in Physiological Theatre), at 5—Prof A E Barclay The Use of X-Rays in Physiological Investigations (2) The Anatomy of the Abdominal Viscera  
KING'S COLLEGE, LONDON, at 5 30—Prof T H Robinson The Myth and Ritual of the Old Testament and the Culture Patterns of the Ancient East (5) Hebrew Myths

## TUESDAY, FEBRUARY 23

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15—Dr Dorothy Russell Intracranial Tumours (1)

## WEDNESDAY, FEBRUARY 24

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4—Dr W S C Copeman The Control of Industrial Rheumatic Diseases in the Future  
BELFAST MUSEUM AND ART GALLERY, at 8—R G Baskett Menus for Farm Animals

## THURSDAY, FEBRUARY 25

KING'S COLLEGE, LONDON, at 3—C J Gadd Assyrian Dealings with Israel  
UNIVERSITY COLLEGE, at 5 30—Sir J J Thomson Physical Lines of Electric Forces and their Application to the Interpretation of the Electromagnetic Field (2)  
KING'S COLLEGE, LONDON (at 40 Torrington Square, WC1), at 6—S P Turin Economic Conditions in Russia To-day (6) Equality of Incomes

## FRIDAY, FEBRUARY 26

UNIVERSITY COLLEGE, at 5 15—Prof A J Clark The Reaction between Drugs and the Cells (1)—At 5 30—Sir E Denison Ross Persia, 1215–1720  
KING'S COLLEGE, LONDON, at 5 30—The Brazilian Ambassador Brazil and its Development  
ROYAL VETERINARY COLLEGE, at 5 30—T M Doyle Diseases of Birds due to Filterable Viruses (2)

## SATURDAY, FEBRUARY 27

HORNIMAN MUSEUM (Forest Hill), at 3 30—J H Driberg Warrior-Herdsman in East Africa

## Museums and the Schools \*

A SMALL pamphlet recently prepared by the Board of Education is of greater importance than its appearance might suggest, in that it brings the whole weight of the Board to bear in favour of the more extended use of museum materials by the various educational establishments of England. The pamphlet begins with a short historical summary, leading to a condensed survey of the present position, it then illustrates its aim by examples from the United States, Germany, Scandinavia, England, and Wales, and finally it indicates methods of co-operation already followed in isolated places as worthy of general adoption. Since no one seriously interested in either museums or practical teaching need grudge the small sum asked or the short time required to buy and study the booklet, it would be inadvisable to prevent him by any more detailed abstract of its contents. The publication does, however, suggest comment on a few of the broader matters involved.

The general question is the use of actual concrete objects in teaching as opposed to mere words. This has of late years been termed 'visual instruction'—obviously an inexact phrase, for 'visual' applies equally to book learning but does not apply to the handling of objects by the blind, which is merely an extreme case of the handling recommended for all pupils by the pamphlet. The use of this concrete method has undoubtedly spread with increasing rapidity during the past half-century, both up from the kindergarten and down from the laboratory. As regards the extremes of the educational scale, not much requires to be said: they have recognised their needs and have provided for them. It is for the intermediate region that missionary work and practical assistance are now desired.

The museums formed by various departments of universities, by art schools, and by technical and commercial colleges serve adequately the wants of those special students for whom they are designed. It is, however, suggested that the material in those semi-private museums might sometimes be made more accessible to the public, and that there might be more co-operation between those institutions and the public museum of the locality. At present it is the schools of art, craft, and trade that make most use of the public museums, the curators welcome visits from such students, and occasionally receive in turn some help in their installations from

\* Board of Education Educational Pamphlets No 87 Memorandum on the Possibility of increased Co-operation between Public Museums and Public Educational Institutions Pp 45 (London H M Stationery Office, 1931) 9d net

the art people. With scientific material the case appears to be different. Curators would no doubt be grateful for more of such help in the determination and classification of their specimens as university professors could render, but when there is a question of a *quid pro quo* it is found that methods of exhibition well adapted to the serious student are not always such as appeal to the public, while it is dangerous to admit pupils—and, sometimes, even professors—to the run of the cases and the free handling of material. With good will and a sympathetic understanding of each other's difficulties, much more could be done to mutual advantage, but in general the best plan is to have distinct collections for distinct purposes.

It is, however, the utilisation of museum material by the secondary and elementary schools that demands chief consideration. It is assumed that almost every school subject, even the teaching of a foreign language (living or dead), may be enlivened by the introduction of illustrative objects. The first question, then, is the provision of such objects. The richest and, in many cases, the only possible source of them is a well-stocked museum, and thus the problem becomes the best means of bringing the class and the collections into profitable contact. Either the school may send its pupils to the museum, or the museum may send specimens to the school. There is much to be said for and against both methods.

Consider, first, visits to a museum. It is plainly the main duty of a curator to place and keep in good order the specimens in his charge. So far as their educational use is concerned, it is his business to display attractive series that shall by arrangement or labelling tell their own story. One consequence of this is that the lesson of the specimens is most easily apprehended in a museum, where also each exhibit is, or should be, seen in its due relation to allied material. The pupils may at the same time be stimulated by the visit, and may be impressed by the surrounding neatness and order. On the other hand, it is maintained by some that the unfamiliar surroundings are distracting, and that the multiplicity of objects hinders concentration. Some museums, therefore, remove objects to a room set aside for teaching, and this enables the specimens to be handled, but only if they are duplicates provided for the purpose. By this compromise the pupils lose some advantages of a museum visit, while the curator and his collections are wrested from the primary purpose of the ordinary museum. The real objection, however, lies in the difficulty of bringing the classes, especially

those from a distance, to the museum, and in the impossibility of each pupil coming to the museum often enough for the visit to take its desired place as a normal part of the curriculum.

We seem, then, to be thrown back on the other method, that of circulating small collections and specially designed exhibits to the schools. Started in Great Britain half a century ago, the method has received remarkable extension in the United States. If it has not grown in Britain in like degree, that is largely due to the lack of interest shown by education authorities. The Museums Association has lately sought to arouse them to a sense of its value, and the present benediction of the Board will doubtless help it forward. Admirable work is being done by several museums on these lines, and success is found to follow expenditure of thought rather than of money. But here again, if every school is to have a supply of material available at the right moment for the appropriate lessons, the number of circulating collections must be multiplied a hundred-fold. At present the collections serve as occasional stimuli, of great value, but far from satisfying the everyday demand. This method, moreover, makes a still greater call on the time of the museum staff, and usually necessitates the acquisition of fresh specimens for the particular purpose. To obviate some of its disadvantages, the Commercial Museum of Philadelphia has replaced circulating loans by gifts of large numbers of identical cases.

Thus we are led to a third method, the formation of school museums. There are many school museums, some excellent, several disreputable, but few on the lines required. What is needed is a collection formed in each school with definite reference to the curriculum. In the establishment of such a collection the pupils themselves should help, guidance and some material can be obtained from the regional museum, and there are other sources from which appropriate specimens can be drawn, but, above all, every teacher should make use of it.

The last remark reminds us that, whatever method be adopted, the immediate task is to teach the teachers. Teaching is their business, it is not the curator's. The use of illustrative objects is more and more being inculcated in the training colleges, and to those who are thus trained the curator can explain the material he sends out and can suggest its use.

To sum up the scheme that seems to be most practicable and promising the best results is a combination of all three methods.—The museum of

the school, in which the school should take a pride, and which should be used to the full in class teaching as well as for spare-time hobbies circulating loans to illustrate some particular, temporary subject, in supplement to the school collections finally, as a reward and additional stimulus, a visit (if possible once a term) to the regional museum, this should be prepared for and should be under trained guidance. It will be long before such a scheme can be in working order, but it is the goal we would set before our educational museum enthusiasts. Meanwhile there are many things that can be done, on which space forbids us to dilate here. Some of them will be found in the excellent pamphlet that is our text.

### Science and Human Life

- (1) *World Chaos the Responsibility of Science* By William McDougall Pp vi + 119 (London Kegan Paul and Co, Ltd, 1931) 3s 6d net
- (2) *The Scientific Outlook* By Bertrand Russell Pp 285 (London George Allen and Unwin, Ltd, 1931) 7s 6d net
- (3) *What Dare I Think? The Challenge of Modern Science to Human Action and Belief, including the Henry La Barre Jayne Foundation Lectures (Philadelphia) for 1931* By Julian Huxley Pp ix + 270 (London Chatto and Windus, 1931) 7s 6d net

IN these three books a psychologist, a mathematical philosopher, and a biologist discuss the relation of science to human life. It is common ground that the application of scientific method has conferred enormous material benefits upon mankind—Prof Huxley's account of the triumphs of applied biology is particularly well done—but in all three writers one discerns a feeling of uneasiness lest science become too powerful and affect prejudicially the harmonious development of man's mind and character.

(1) Prof McDougall roundly asserts that the physical sciences are mainly responsible for the present world chaos, for they "have produced a complexity of our civilization which far outruns our present understanding and power of control." He would seek a remedy in more science, but in science of a different kind in a thorough study of social and economic problems from a definitely psychological point of view. This point of view would be completely different from that of the physical sciences—McDougall entirely rejects the mechanistic treatment of life and mind as inadequate, and substitutes his own conative or

hormic conception. His book is vigorously written, and his remarks on the present world crisis are extremely apt and timely.

(2) Mr Bertrand Russell has much more faith in the value of mechanistic methods in biology and psychology, and in effect denies that any other method is scientific. His psychological gods appear to be Freud and Pavlov. We venture to think that he has been over-impressed by the claims of mechanistic biologists, and that with greater knowledge would come a less dogmatic attitude. His book is an interesting one, and deals in a skilful way, and not without a certain dry humour, with the principles of scientific method. Chapters on scientific metaphysics and science and religion give him an excellent opportunity, of which he takes full advantage, to criticise Jeans and Eddington in their excursions into philosophy.

The most significant part of the book, in our opinion, is the short last chapter on science and values. It follows a vivid presentation of what the world State of the future might be like if it were organised on purely scientific lines—a picture which, Mr Russell agrees, is in some aspects nightmarish and depressing. Already in his introduction Mr Russell had pointed out that if "a scientific civilization is to be a good civilization it is necessary that increase in knowledge should be accompanied by increase in wisdom", meaning by wisdom a right conception of the ends of life. Science by itself can give no guidance as to values or ends. A society deliberately constructed on scientific principles, without regard to values, might then be a very bad society.

If we read Mr Russell aright, he views the possibility of a scientific world State with grave misgiving, and this because the power over Nature which science gives may come to be regarded as an end in itself. The love of knowledge, from which science springs, has, Mr Russell tells us, a twofold origin. "We may seek knowledge of an object because we love the object or because we wish to have power over it. The former impulse leads to the kind of knowledge that is contemplative, the latter to the kind that is practical. In the development of science the power impulse has increasingly prevailed over the love impulse" (p 270). "The scientific society of the future as we have been imagining it is one in which the power impulse has completely overwhelmed the impulse of love, and this is the psychological source of the cruelties which it is in danger of exhibiting" (p. 273). Power cannot legitimately be regarded as one of the ends of life, but merely as a means to

what the Greeks knew as 'the good life', if science, which is power, subserves the proper ends of human life, well and good, if it does not, disaster will follow

(3) These views, with which all thinking men will agree, are closely paralleled in Prof Huxley's discussion of scientific humanism. He agrees with McDougall that the rapid increase in scientific knowledge and the spread of the scientific spirit—meaning by this the predominantly materialistic method—are largely responsible for the chaos in thought which is characteristic of the present day

"The multiple contradictions sum up along these lines—that in the sphere of control over environment and destiny, man is through science being given fabulous and undreamt-of powers, yet is by no means agreed as to how to employ them. And that in the sphere of thought, while the scientific picture of the universe, in which naturalism and determinism rule, grows ever more triumphant and complete, yet it becomes ever more sharply set off from the world of values in which the human spirit inevitably has its being. Science, in a word, both in the outer and the inner life, has come up against human nature, and each seems in a strange confused way to be barring the progress of the other. Science and human nature—there lies the chief unresolved antinomy of the present stage of our civilization" (p 124)

The reader will find much to interest him in Huxley's extended treatment of this theme and in his sketch of a non-theistic religion compatible with evolutionary science

The problem raised in different ways in these three books is by no means a new one. It is certain that if science continues along purely naturalistic lines, if it rests content with the abstract and schematic treatment of reality from which it has derived so much of its practical power, it must remain apart from, and opposed to, the world of values

Science can in no case become an arbiter of values, but we may suggest that the antinomy of which Huxley speaks may possibly be overcome if a more concrete, more objective method establishes itself in biological and psychological research. If, for example, it can be shown that conation and perception are indispensable concepts in the study of animal behaviour, the way is opened towards a less abstract and analytical treatment of some at least of the problems of biology, and a bridge built across to the sciences of human psychology and sociology, upon the importance of which for the future development of civilisation McDougall rightly lays such stress

## International Geology

*International Geological Congress Comptes rendus of the XV Session, South Africa, 1929* Vol 1. Pp xiv + 314 + 42 plates Vol 2 *Scientific Communications* Pp x + 688 + 97 plates (Pretoria Wallach's, Ltd, 1930) 2 vols, 40s

THE two handsome and beautifully illustrated volumes which record the proceedings of the fifteenth session of the International Geological Congress, held in South Africa during July and August 1929, and the scientific communications there presented, constitute a worthy account of a meeting which was of outstanding importance because of the interest and success of the excursions and the high quality of the papers read. The first volume is occupied by minutes and official memoranda, and by long accounts of the excursions, enriched with a liberal photographic record. Those who attended the Congress will turn with renewed pleasure to these pages, while those who were unable to make the long journey will find in them verbal and pictorial compensation. The second and larger volume contains 78 papers, dealing with special subjects chosen for discussion and with general geology. In addition to the usual English, French, and German, two newly admitted languages, Spanish and Italian, appear on this occasion, accompanied, however, by summaries in English or French. The sections devoted to pre-Pleistocene glacial periods, the Karroo system, and rift valleys are of leading importance, and all contain contributions that substantially advance the boundaries of geological knowledge, particularly as regards the areal and historical geology of Africa.

Of all countries, so far as we know at present, South Africa is the richest in its evidences of early glaciations. Rogers summarises the indications of glaciation in the Witwatersrand and Transvaal systems and directs attention to a pre-Nama tillite in Namaqualand. A glacial band in the Table Mountain series is described by Haughton. The world-famous Dwyka glaciation is appropriately dealt with by du Toit in a summary account that is a model of its kind. He shows that there were several glacial phases which probably began about the end of the Lower, and died out not later than the close of the Upper Carboniferous. Turning to Asia, Norin records the discovery in 1928 of late-Palaeozoic glacial deposits in the mountains bordering the Tarim Basin on the north, and Backlund describes a probable tillite of similar age from the northernmost Urals. These lend weight to Gortani's

contention that no amount of continental drift will serve by itself as a primary explanation of pre-Pleistocene glacial epochs, even though the drift hypothesis may be necessary to provide an escape from the obvious geographical difficulties. Gortani favours fluctuations of solar radiation as the fundamental cause of terrestrial climatic variations. Lower Cambrian tillites occurring in the Yenisei Ridge of Siberia were examined in 1927-28 by Nicolaev, who presents a convincing and well-illustrated account of their glacial characters.

The Karroo rocks of Africa and their correlation are ably dealt with by Dixey. In the South African basin, these formations reach a thickness of 26,800 feet. In the Shire-Lower Zambesi area, 18,000 feet is reached. This province of the Karroo is admirably described by Dixey in a separate paper. The Rhodesian basin (Wankie-North Nyasa) contains a maximum thickness of only 4200 feet, this area, and the Tanganyika basin near Tanga, where 10,000 feet of Karroo sediments occur, are also described by Mennell. Teale shows that the so-called 'Tanganyika system' includes Karroo rocks, and possibly Waterberg and Transvaal formations. The basin of the Belgian Congo, which encloses the largest known outcrop of the Karroo in Africa, is dealt with in great detail by Fourmarier.

The Abyssinia-Somaliland occurrences are mentioned by various authors, and notably by Stefani. Range describes the Karroo of South-West Africa with special reference to its flora and fauna. Borges and Mouta give an account of the Angola representations of the system, accompanied by a coloured geological map of the south of Angola. The widespread prevalence of the Stormberg basalts, with rhyolites in association in many areas, is a remarkable feature that is well brought out by the papers and maps of this section. A short review of the Karroo flora is given by du Toit, with a hypothetical continental restoration showing the distribution of the chief genera in the various members of Gondwanaland. Walkom compares the fossil floras of Australia with those of South Africa, and Haughton deals with the Karroo Reptilia.

A most important discussion of the African rift valleys is contributed by Wayland, with a tectonic map of Uganda. He finds the tension hypothesis to be untenable, and gives much additional evidence supporting the alternative hypothesis, for which he was originally responsible, that the Western Rift and the uplifted massif of Ruwenzori are the result of deep-seated compression. A valuable systematic

study of the geomorphological aspects of rift-faults by Johnson provides a series of pictures of all the leading possibilities, which should aid the field geologist to find the critical evidence required for correct interpretation in any particular case. The European *graben* are discussed by Seidl and Seidlitz, the latter adding much new information about those of Syria and Erythraea. Van Rhedan deals with the buried graben of South Limburg. Harrison describes the Magdalena trench of Colombia, this is 400 miles long by 40 miles wide, and is 4000 feet deep. It broke in during the early Tertiary, and volcanic activity has been prevalent, and still continues, along the western edge.

The section on magmatic differentiation is disappointing in that no new conclusions of petrogenetic significance are reached. Niggli gives a general discussion, Reuning presents a chemical study of the magmatic provinces of South and South-West Africa, and Vardabasso deals with the Predazzo province. The latter is interesting in that it provides evidence that masses of Permian quartz-porphyrines were probably regenerated as granite in Tertiary times. In the General Section a study of the noritic lopolith of Sierra Leone is recorded by Junner, with many new analyses by Harwood and Theobald. The structure and mineralisation of the Kambone copper mine in Katanga is described with a wealth of illustration by Schulling, and the copper zone of the Katanga-Rhodesian frontier is dealt with more broadly by Thoren.

The geology and tectonics of North Africa and adjacent regions are considered in a series of papers by Russo on the relations of the Rif to the Atlas and the Betic Cordillera, Neltner on Morocco, Maddelena on the Jurassic submarine volcanic rocks of Sicily and the tectonics of Sicily and Tunisia, and Solignac on Tunisia as a whole. French Indo-China is well described by Blondel, Portuguese East Africa by Freire d'Andrade, and the Central Massif of France by Demay.

In the section on petroleum, Sacco again suggests an inorganic origin for the petroleum of Italy, basing this view on the association with plutonic and volcanic rocks and, in Sicily, with beds of sulphur. Fabian records his belief that the petroleum of Sicily has a deep origin, and that it migrated during the Pliocene through highly folded and faulted pre-Triassic rocks that are otherwise impermeable. Other papers deal with the geological work of micro-organisms, and with the modern floras of the Pretoria and Vryburg districts in relation to the local geology.

An announcement of the greatest interest is made by Kovaloff in the course of an account of the present spectacular activities of the Russian Geological Committee. For 1932-33 the Five-Year Plan allows nearly £6,000,000 for geological work, and 1300 field parties are expected to be engaged in survey and economic investigations. A doubt is expressed as to the possibility of finding the number (3200) of qualified geologists required. In 1928-29, 950 geologists were at work, and the practical results already achieved demonstrate, on a scale hitherto unprecedented, that geological research is a fundamental necessity to national welfare in general and to industrial progress in particular.

### Experimental Teratology

*Connecting Laws in Animal Morphology* Four Lectures held at the University of London, March 1929. By Prof Hans Przibram. Pp 62 + 8 plates. (London: University of London Press, Ltd, 1931) 4s 6d net.

THE future historian of biology will doubtless count among the more important tendencies of the first quarter of this century the extended application of the experimental method to all kinds of biological problems. More especially the phenomena of growth and form, which previous generations had, for the most part, been content to observe unfolding in Nature, are now studied in the modifications induced under artificially controlled conditions. In this department of research, Prof Hans Przibram has been one of the pioneers. Some twenty-five years ago he founded in Vienna a Biological Experiment Station, provided with arrangements for keeping large numbers of living animals under constant and carefully adjusted conditions. A long series of important researches have since been carried out at this institution by him and his pupils.

In 1929, Prof Przibram gave a series of four lectures in University College at the invitation of the University of London, and he has now published these under the title "Connecting Laws in Animal Morphology". Those who had the good fortune to hear these lectures, and many who had not, will welcome in this permanent form the exposition of what this distinguished representative of the experimental school regards as the most significant results obtained by the experimental method.

The first lecture, on "Organisation", deals with 'the increase in differentiation' as shown in the

modelling of a limb out of a formless mass of undifferentiated cells in the regeneration of a crustacean's claw. The 'reversal of asymmetry', discovered by Przibram in 1900 to take place after the removal of the large claw in certain prawns, is interpreted as showing "the advantage of an earlier start". In those decapod Crustacea in which the claws are of different form and size on the two sides of the body, the larger, more specialised claw has simply outstripped in growth its smaller, more primitive partner. If it is sent back to the starting-point by amputation or autotomy, the smaller claw takes the lead and, with increased size, attains increased differentiation.

This example serves to show at once the strength and (as it seems to an old-fashioned systematist) the weakness of the experimental method. It will not be disputed that Przibram has made good his claim to have discovered a 'connecting law' in animal morphology. His experiments have defined one of the conditions under which asymmetry reveals itself. He shows that, other things being equal, increasing size is accompanied by increasing differentiation. So far as they go, his conclusions rest on a secure basis of fact. But, do they go very far? Have we really learned anything as to the origin or the nature of asymmetry? The systematist, studying the bewildering complexity and variety of the forms assumed by the large claw of the alpheid prawns, for example, will feel little satisfaction in the explanation that it is more complex because it is bigger than its fellow. Is the very indistinct photograph of *Alpheus* which the author thinks good enough to illustrate his results a symbol of his undue simplification of the problem?

The lecture on "Growth" discusses the fact that in a number of arthropods the ratio of increase in linear measurements at each ecdysis is approximately 1.26, that is to say,  $\sqrt[3]{2}$ . Przibram is so impressed with this evidence of the doubling of mass (confirmed in some cases by weighing) that he calls 1.26 "the magic number". "Doubling of mass in the living being we may then assume to be the counterpart of chemical mass-action: the product of reaction being proportionate to the molecules involved." Perhaps the biochemists may find this statement satisfying. What the simple zoologist fails to understand is why this doubling of mass should be associated with ecdysis. The association is not invariable. Przibram, it is true, dismisses as abnormal the cases of starved or injured animals which go on moulting without increase (or even with diminution) of mass. But is the correlation so close

and so invariable even in normal growth? If it is not, a good deal of the magic will have faded from  $\sqrt[3]{2}$

Prof Przibram in his preface mentions "quantitative formulation" as one of the prime necessities for the building up of biological theories. We are reminded of Eddington's remark "by the time the serious application of exact science begins we are left with only pointer readings." But all pointer readings are not necessarily significant, and the half-mystical contemplation of numerical relations has before now led biologists into the wilderness.

The other lectures similarly leave one with the impression that experimental morphology (or experimental teratology) does indeed provide conclusive answers to the questions dealt with, but fail to convince one that these questions are always of primary importance. At all events, there is no need, yet awhile, to lay aside as useless the older methods of comparative morphology and taxonomy.

### An American Palæontologist

*Cope, Master Naturalist the Life and Letters of Edward Drinker Cope, with a Bibliography of his Writings classified by Subject, a Study of the Pioneer and Foundation Periods of Vertebrate Palæontology in America*. By Henry Fairfield Osborn, with the co-operation of Helen Ann Warren. Pp xvi + 740 + 24 plates. (Princeton, N.J. Princeton University Press, London Oxford University Press, 1931) 22s 6d net.

THE modern school of vertebrate palæontology in North America has achieved such remarkable results that its history cannot fail to be of interest. When this is combined with the life-story of perhaps the most brilliant of the three pioneers who started it, the narrative becomes still more absorbing. We are therefore much indebted to Prof H. F. Osborn for the labour he has bestowed on the handsome volume in which he describes the life and labours of Edward Drinker Cope and determines his place in American science.

Cope, who was born in 1840 and died so long ago as 1897, was an observant naturalist from early childhood, and, until misfortune overtook him in the 'eighties, was well provided with means to follow his inclinations. Even then his enthusiasm never failed, and a call to a professorship in the University of Pennsylvania enabled him to pursue his researches to the end. He began his studies of

fossils just after Darwin had convinced the scientific world of the truth of the doctrine of organic evolution, and he was always trying to recognise pedigrees among the successive extinct animals which were revealed by the fossils he collected. In a general pioneer way he met with much success, and his two volumes on "The Origin of the Fittest" (1887) and "The Primary Factors of Organic Evolution" (1896) summarise the many new facts and ideas with which he enriched palæontological science.

Prof Osborn begins with an interesting chapter on the early students of American vertebrate fossils who preceded Leidy, Cope, and Marsh. He then tells the story of Cope's life and work, mainly by well-arranged extracts from Cope's own letters to his family. A chapter follows on "How Cope earned the Title of Master Naturalist", and this affords an opportunity of discussing the main features of Cope's contributions to natural science, with some reference to his attitude towards education, sociology, politics, and religion. The next chapter is devoted to the personal reminiscences of Prof Osborn during his twenty years' association and friendship with Cope. The last hundred and fifty pages are occupied with a useful list of Cope's very numerous writings, classified under subjects.

Cope was associated with Philadelphia for the whole of his life, and belonged to the Quaker community. Most of his letters reflect his upbringing, and some portions are beautifully expressed. His quarrelsome rivalry with Marsh, however, occasionally led to outbursts which he could scarcely have wished to be preserved in print, and our only criticism of the book is that the account of the Cope-Marsh controversy might have been judiciously curtailed.

A S W.

### Colloids

*Colloids*. By Dr Ernest S Hedges. Pp vii + 272. (London. Edward Arnold and Co., 1931) 12s 6d net.

DR HEDGES' book is by way of being a *tour de force*. He has taken a subject the development of which has involved the use of a not inconsiderable mathematical apparatus, and has discussed it, lucidly and very fully, without the use of a single mathematical symbol, save when, on occasion, he quotes a formula as a shorthand way of stating a result.

There is much to be said for the method. We are apt nowadays, when gazing full of awe at an

imposing mathematical structure raised on a few premises of doubtful validity, to forget the truth that underlay Sir William Hamilton's attitude towards mathematical studies. After all, mathematics can become (and very often confessedly is) a mechanical routine, designed to save thought rather than to promote it. Such a mechanical exercise is a dangerous habit for a student of physics. True, the opposed habit of picturing mechanical models and 'explaining' phenomena in terms of them is not without its dangers, but, tried by a pragmatic test, it probably comes off best. Dr Hedges' attitude is well summed up in his own statement that a mental image of the processes involved is best obtained "not by regarding the colloidal system as the unit, but rather by considering the processes from the point of view of the colloidal particle itself. Only by getting down to the colloidal particle . . . in imagination can this vivid picture, which is essential to the proper understanding and appreciation of colloid chemical principles, be obtained."

From this point of view Dr Hedges discourses on polyphase systems, the formation of colloid particles, the general characteristics of colloid systems, methods of colloid investigation, the electrical properties and the stability of colloids, hydrophobic and hydrophilic colloids, and the detailed properties of gels. These last-named properties are discussed at considerable length, inasmuch as "natural colloids appear more often in the form of gels than sols, and biological and other reactions normally take place in gels."

The volume closes with a short chapter, which we should like to see considerably extended, dealing with such practical applications of colloidal principles as may be included under the headings clays and soils, dyestuffs, leather, milk, wool, water purification, sewage disposal, and so forth. It will be seen that flotation processes are not discussed, and, if we may venture a criticism, the sections which deal with surface forces are more sketchy than any others in the book and might very well be elaborated.

The book as a whole may be commended. It would be a mistake, in a new edition, to destroy its essentially non-mathematical character, nevertheless, we hope that, should a new edition be called for, Dr Hedges will, for the benefit of the weaker brethren, add a mathematical appendix which shall deal briefly with such topics as adsorption, the Brownian movement, and surface energy.

## Short Reviews

*Newton the Man* By Lt-Col R de Villamil  
Pp vi + 111 (London Gordon D Knox)  
3s 6d net

THIS book has two outstanding and most valuable features. Col de Villamil has, by a piece of fortunate and painstaking research, found the detailed inventory of Newton's effects that was compiled by virtue of the Commission of Appraisal under the seal of the Prerogative Court of Canterbury on April 18, 1727. To the student of Newton the book is fascinating reading, throwing as it does the most intimate light on the later environment of England's greatest man of science. The dominant note is crimson frugahty! Luxury and æsthetic taste are conspicuously absent. We know from Humphrey Newton that Newton was the reverse of self-indulgent, and also that in matters of personal appearance he was careless, not to say definitely untidy. The inventory suggests that these general characteristics persisted all his life, even in his later years of affluence.

Perhaps the most important item in the inventory is the library. That catalogued in the British Museum and known as the Huggins Catalogue represents the books purchased by Huggins at the time of Newton's death. For nearly two hundred years all trace of this library has been lost, but, thanks again to the industry of Col de Villamil, a very large part of it has been rediscovered and examined. He had the good fortune to find the Musgrave Catalogue of a library that comprised a large number of volumes from the original Newton library purchased by Huggins.

A careful comparison of these two catalogues shows that many volumes which appear in the Huggins are absent in the Musgrave Catalogue. What has become of them is a complete mystery, but one most important fact emerges from the later discovery. The books in the Musgrave Catalogue (compiled about 1760) have all been carefully 'press-marked', consequently, the appearance of this 'press-mark' in any isolated volume is sure evidence that it originally formed part of this library. In fact, Col de Villamil has already been able to identify one stray volume by this particular evidence.

The book is a real contribution to the literature of the history of science. V E P

*Chaucer on the Astrolabe* With the Original Illustrations. Second and abbreviated edition revised by R T Gunther. Pp iv + 92 (Oxford R T Gunther, 5 Folly Bridge, 1931) 7s 6d net

THIS is a reprint in a separate form of Dr Gunther's modernisation of Chaucer's treatise on the astrolabe, which formed part of vol 5 of his series, "Early Science in Oxford", reviewed in NATURE for April 12, 1930 (p 556). A few verbal alterations have been made, and the work has been entirely reset, so that his description of the work as a second edition may pass, though it is not bibliographically accurate. The book is of

importance, as its appearance coincides with that of the first modern astrolabe, and it is of interest to compare Chaucer's treatise with that of Prof Jenkin, who is responsible for the new instrument. Dr Gunther may justly claim a share in the revival of the astrolabe, and we may account it not the least of his services to science.

The instrument, as it is now offered to the public, is much simplified. It consists of a metal plate some eight inches in length to which is attached a circle with the various graduations and arcs of the 'mother', substantially as described by Chaucer. Concentrically with this, a transparent plate with its appropriate graduations and circles revolves over it. Finally, a revolving transparent rule with ebony sights enables an observer to read off the angular altitude of any object on the scales of the astrolabe. On a previous occasion we have remarked on its utility—"nearly every instrument used for observation in Physical Astronomy is a part of a perfected astrolabe"—and though the modern instrument is by no means as decorative as a medieval astrolabe, it should, under the direction of a competent teacher, be a first-rate introduction to the practical study of astronomy.

The placid ignorance with which the modern city-bred man contemplates the heavens is a standing reproach to our schools and colleges. Dr Gunther's work reminds us of the estimation in which a knowledge of the subject was once held, let us hope that his efforts will reinstate it in the favour of our educational authorities.

*Communication Networks*. By Prof Ernst A. Guillemin. Vol. 1. *The Classical Theory of Lumped Constant Networks*. Pp xii + 425. (New York: John Wiley and Sons, Inc., London: Chapman and Hall, Ltd., 1931.) 25s net.

WE think this book will help forward the theory of the steady and transient currents which occur in communication networks. The author is obviously thoroughly at home in higher mathematics. He points out that, if research is to progress, new methods of attacking the network problems that occur in practice must be devised. After starting with general remarks on mathematical methods and analogies, he inserts two chapters on the simple mesh circuit before he gives the fundamental principles. Although perhaps illogical, it is an excellent method of introducing the subject, as the reader can then see the reasons for the procedure in the general case.

No proof is given of Heaviside's formula, as it would presuppose too great a knowledge of advanced theory. The author points out that Heaviside's formula is not a quick method of getting the complete solution. It involves the same amount of mechanical labour as the classical method. But it is an extremely compact method from the point of view of analytic form. In practice it is not much used, but in research work, when the properties of complicated networks have to be investigated, it is very useful owing to its compactness. We are looking forward to the second volume, where the author will discuss the classical theory of lines, cables, and filters.

*Die Schadlingsfauna Palastinas unter besonderer Berücksichtigung der Grossschadlinge des Mittelmeergebietes*. Von Dr F. S. Bodenheimer (*Monographien zur angewandten Entomologie. Beihefte zur Zeitschrift für angewandte Entomologie*, herausgegeben von Prof Dr K. Escherich, Nr. 10). Pp xv + 438. (Berlin: Paul Parey, 1930.) 42 gold marks.

THIS volume forms a comprehensive monograph on the injurious insects of the eastern Mediterranean region. It is based in the main upon the author's own experience, during the past eight years, in dealing with the insect enemies of cultivated plants in Palestine. A very large number of individual pests are noticed, and the more important are discussed at length, with accounts of their biology and methods of control. The introductory chapters are concerned with general principles, and special reference may be made to those dealing with ecological and climatic factors. There are also sections dealing with the insecticides, pests of stored products, forest pests, and beneficial insects. A book of this kind should form a valuable stimulus to entomology in the Near East, and it can be recommended as being reliable and up to date in character. It is exceedingly well indexed and fully illustrated.

*Genetics and Eugenics: a Text-Book for Students of Biology and a Reference Book for Animal and Plant Breeders*. By Prof W. E. Castle. Fourth revised edition. Pp x + 474 + 66 plates. (Cambridge, Mass.: Harvard University Press, London: Oxford University Press, 1930.) 12s 6d net.

SIX years have passed since the third edition of this work appeared, but so rapid are the additions to knowledge of genetics, and so rapid also the changes of opinion of geneticists, that several alterations are noticeable. Polyploidy, parthenogenesis, artificial mutations, selection are all treated anew, and more is said of heredity amongst mankind; there is a fresh chapter on biometry and its calculations, and the bibliography of selected papers covers sixty pages. But the book is so well known as a concise and clear exposition of its subject, that it need only be said that the fourth edition improves upon its predecessors.

*The Mediaeval Latin Versions of the Aristotelian Scientific Corpus, with Special Reference to the Biological Works*. By S. D. Wingate. Pp x + 136. (London and Leamington Spa: The Courier Press, 1931.) 10s 6d net.

THIS scholarly essay on a very important question of history will be welcomed by all those who are interested in the development of science and philosophy. Dealing with actual facts, the author explains how the works of Aristotle came to be known to the West in the Middle Ages. He traces the Latin translations of the "Aristotelian Corpus" through the Arabic, Byzantine, and medieval versions, and discusses their merits and their influence.

T. G.

## The Cause of Cancer

DR W E GYE,\* rightly we believe, thinks that the problem of the causation of cancer is at present most likely to be solved by studying the malignant tumours of fowls first described by Rous twenty years ago. Ordinary mammalian tumours, either arising spontaneously or induced by tarring or other irritating procedures, can be transmitted from one animal to another only by transplanting living tumour cells. The Rous tumours are peculiar in that they can be transmitted by means of dead cells, by cell-free extracts, and by such extracts after they have been passed through fine filters which will detain ordinary bacteria. In other words the filtrates contain some carcinogenic agent which resembles an ultra-microscopic virus, and Drs Gye and Purdy now give an account of the multitudinous experiments which they have made in an attempt to ascertain the nature of this agent.

In Gye's original paper published in 1925, he advanced the view that the agent is made up of two factors—one, the virus, can be killed by chloroform or acriflavine, the other, the specific or intrinsic factor, is a labile unorganised substance easily destroyed by gentle heating. An extract inactivated by chloroform could be reactivated by the addition of an extract inactivated by heat. He also found that an extract of a Rous tumour which had been chloroformed could be activated by a heated extract of several mammalian tumours, and would produce a Rous tumour on inoculation into a chicken. Whence he concluded that there was a general non-specific virus which might cause any tumour if it could co-operate with the specific factor which was responsible for the maintenance of the characteristic histological constitution so definitely characteristic of all transmissible neoplasms. The virus was looked upon as an independent organism coming into the body from outside, the specific factor as something arising in the cells of the affected animal.

As the result of a great deal of further work, in which his exacting standard of technical rectitude is fully maintained, Dr Gye is still of opinion that this interpretation is in the main correct, but he admits that its original experimental basis has proved less secure than he had supposed. Extracts can be inactivated with certainty and regularity by mild heat, but he has found that the actions of phenol, acriflavine, and chloroform are less dependable and that extracts which have been treated with these antiseptics in such a way that they can be relied upon to be inactivated every time the experiment is tried cannot be reactivated by heated extract "Antiseptics", as he says, "kill the virus only a very little more readily than they destroy the intrinsic substance". Hence it is impossible to get a long series of consistent clean-cut results which will convince the

sceptic, though the mass effect leaves the author's own opinion much as it was.

Dr Gye then turns to immunological observations and describes a long series of experiments on the properties of the blood serum of animals which have been injected with tumour extracts. This section of the book (p 307 onwards) contains a great number of important and interesting data in a field which has been little explored, and their apprehension is greatly helped by exceptionally clear diagrams. A detailed summary is impossible, but the chief conclusion which emerges is that the sera of the inoculated animals contain two different antibodies, one of which renders an active tumour extract ineffective after it has been heated to 55°C for half an hour (that is, in bacteriological language, in the absence of complement), while the other neutralises the extract only if fresh serum (complement) is present. If there are two antibodies, there are presumably two antigens which confirms the original hypothesis of a dual agent.

A second discovery of moment is that the sera of goats repeatedly injected with extracts of normal chick embryos will neutralise active extracts of Rous tumour in the presence, but not in the absence, of fresh serum, and that this property can be abstracted from the sera by adsorption with minced chick embryo. Embryo also removes the antibody which needs the presence of fresh serum from the sera of goats inoculated with Rous extracts, but has no effect on the antibody which is active in the absence of fresh serum: the former is the antibody to the specific factor, the latter to the virus. Anti-Rous sera also inactivate extracts of other fowl tumours of quite different histological structure, which therefore presumably contain the same virus, in one instance this does not happen in the absence of fresh serum, and hence the virus is judged to be different.

Such in brief are Dr Gye's main results and inferences. He has much evidence in their favour, but there is obviously a good deal that needs further explanation, and the experiments do not always seem consistent among themselves. As he himself says, the method of testing by inoculating fowls is at best calculated to reveal only coarse differences, and the effect of some tumour extracts is complicated by the presence of elusive "inhibitory substances". The serum from normal guinea-pigs, goats, and fowls occasionally neutralises active extract, ducks injected with Rous extracts yield sera on which complement has no effect, rabbits generally produce no antibodies, goats generate both antibodies, a horse showed both antibodies and indications of a third. A goat immunised with Rous filtrates was bled on July 25 and the serum tested next day was found to be active only in the presence of complement (p 344), serum obtained from the same animal on June 30 and tested on Aug 29 neutralised well in the absence of complement.

It may be that curiosities and apparent dis-

\* The Cause of Cancer. By Dr W E Gye and W J Purdy. Pp. xiv+515. (London, Toronto, Melbourne and Sydney: Cassell and Co., Ltd., 1931.) 30s. net.

crepancies such as these are the necessary consequences of not having always an infecting extract of standard strength against which to test the sera, but it is difficult to get rid of a suspicion that the distinction made between the two antibodies is quantitative rather than qualitative, and that their relation to fresh serum is not that of immune body and complement as known in bacteriology. The whole narrative needs, deserves, and will doubtless receive detailed critical analysis. It is fortunate that the data are presented on such an ample scale that this is possible. The interpretation seems also in places to be inconsistent. Thus on p 354 it is pointed out that two goats injected with heated extract (that is, containing virus only) produced sera which were active only in the presence of complement and therefore contained antiviral bodies only, and that this assumption is in accordance with general bacteriological experience. It is difficult to see how this fits with the fact (p 361) that anti-normal-embryo sera are also active only if fresh serum is present. On p 421 the antibody which operates in the absence of fresh serum is definitely identified with the extrinsic factor, that

is, the virus. Nor is it possible to subscribe to Dr Gye's suggestion that his immunological experiments demonstrate that extracts of fowl tumours contain some antigen which cannot have originated in the fowl and must therefore be an extrinsic virus which he thinks is widely disseminated about the world. Immunological differences between proteins depend on differences in chemical structure rather than on differences of biological origin, though in a rough way the two generally go together. Antigens from different species may be indistinguishable (blood serum of sheep and goat, egg albumin of duck and hen, various caseinogens), while antigens from the same species may be different (for example, the proteins of blood plasma or egg white) and the proteins of the lens of the eye may be antigenic in the individual to whom the eye belongs.

It seems evident that this part of Dr Gye's argument will not carry anything like the weight that he has put on it. What his observations do seem to show quite clearly is that part at any rate of the agent is intrinsic—a conclusion in good accord with the old-fashioned view that cancer is a local autochthonous disease.

### Scientific Research and National Life \*

THE sixteenth Annual Report of the Department of Scientific and Industrial Research covers the period Aug 1, 1930–July 31, 1931. It includes the brief report of the Privy Council, signed by the Right Hon Stanley Baldwin, and the longer report of the Advisory Council, over Lord Rutherford's signature, which surveys the development of the Department and emphasises the need for scientific method in industry. Summaries of the work carried out by the National Physical Laboratory, the Chemical Research Laboratory, the research associations, and under the direction of some forty-five research boards and committees are attached, together with appendices dealing with finance, publications, and the personnel of the various boards and committees. The report presents an impressive picture of the contribution which science is making to the major needs of the population, promoting not merely material development, but also the growth of a better and healthier social order. Not only the research associations, but also the long list of committees and boards, many of whose distinguished members are rendering voluntary service which is little recognised, may be regarded as a great general staff organised for the application of science to the myriad needs of modern society.

In view of the curtailment of expenditure by the Committee of the Privy Council, particular attention is attracted to the expenditure detailed in the present report. The gross estimate for the year is £740,520, of which £30,340 is for headquarters administration, but receipts amounting to £184,829 bring the net expenditure to £555,691. Grants for

research account for an expenditure of £40,610, gross, the Geological Survey and the Museum of Practical Geology for £67,714, and grants to research associations for £75,655. The National Physical Laboratory represents a gross expenditure of £208,964, of which slightly more than half, £104,706, is recovered as receipts from outside bodies and firms, the Air Ministry, and other government departments or special research funds. The Chemical Research Laboratory represents a charge of £19,993 net, building research, £30,421 net, fuel research, £87,411 net, radio research, £12,066 net, water pollution, £10,020 net. More than three-quarters of the expenditure of £50,060 on food investigation is borne by receipts, the net cost to the State being £11,693. Receipts amounting to £6936 similarly reduce the expenditure on forest products research to £36,376.

The expenditure on research associations, of which twenty-one received grants during the year, is of special interest. The seven largest grants, of £15,800, £8452, £8000, £7500, £6500, £4800, and £4750, are those paid to the Cotton, the Scientific Instruments, the Non-Ferrous Metals, the Wool Industries Research Association, the National Federation of Iron and Steel Manufacturers (Industrial Research Council), the Cast Iron Research Association, and the Research Association of the British Paint, Colour, and Varnish Manufacturers. The British Photographic Research Association was liquidated on Nov 7, 1930, and its functions have now been taken over by the research establishments of the rationalised photographic industry. Thus the total expenditure of £26,597 spread over twelve years has in this instance fully realised the objects of the Government scheme, and paved the way for

\* Department of Scientific and Industrial Research. Report for the Year 1930–31 (Cmd 3989) Pp iv+186 (London: H.M. Stationery Office, 1931) 3s net.

the future development of the research by the industry itself independently of financial assistance from the State. The report states "There can be no doubt that the important scientific investigations carried out by the research association during the period of its existence have materially contributed to the marked improvement in the quality of the photographic materials and accessories produced by British firms in recent years, and the Department has received an assurance that provision will be made under the new regime for the continuance of researches of this character."

The Wool Industries Research Association anticipates that the voluntary levy scheme will be working on normal lines next year. The Research Association of the British Motor and Allied Manufacturers is also being wound up, and its place is being taken by the Research and Standardisation Committee of the Institution of Automobile Engineers, which will receive grants from the Department up to a maximum of £2500 per annum for three years on a pound for pound basis in respect of income raised by the industry above £3000 a year. A further departure was the formation in November 1930 of the Printing Trades Research Association, which, however, is not in receipt of a grant.

Viewing the work of the research associations as a whole, the opinion is expressed that their achievements thoroughly justify the expenditure incurred, but the outstanding difficulty experienced by the research associations is that of bringing home to their members the practical significance of their work. This difficulty is being overcome, sometimes by the establishment of development departments, sometimes by the appointment of liaison officers.

Space does not permit even an outline of the work of individual research associations, and reference can only be made to a few features. The Cast Iron Research Association has developed the 'Sisal' heat resisting alloys which are finding successful use in industry, and the application of the knowledge of moulding sands and refractories acquired as a result of the Association's investigations represents an estimated annual saving to the industry of about £100,000 a year. The Non-Ferrous Metals Research Association has been responsible for important advances in the investigation of aluminium castings and in the comparative study of a range of bearing metals and their interaction with representative lubricants. Investigations carried out by the British Refractories Research Association to improve the durability of refractory materials have an interest not only to the ceramic but also to the iron and steel and other industries concerned with high temperature operations, while much of the work carried out by the Electrical and Allied Industries Research Association is definitely related to matters of public safety and economy, for example, in the factor of safety and design of overhead transmission lines in the 'grid' system, and in the laying of electric cables at considerable depth.

The Scientific Instruments Research Association records the interesting discovery that the effect of

polishing the surface of any glass, almost without exception, is to raise the refractive index of the immediate surface layer, an observation which should yield considerable information about the mechanism of polishing. The Paint Research Association has been concerned with the practical methods developed for the measurement of colour and the determination of colour fastness of pigments, and a table of fastness based on the quantitative methods developed is rapidly being accepted by the industry as the basis of colour valuation of pigments. X-ray methods are also being employed for the investigation of the structure of pigments, steels, metal deposition, and scales on steel.

The Cotton Industry Research Association has undertaken a long programme of fundamental studies on the physico-chemical nature of dye solutions and of the dyeing process, and these co-ordinated researches should fill a gap of much technical importance in our knowledge of the relation of the nature of dye solutions to the mechanism of cotton dyeing and the properties of the dyed material. In addition, laboratory work on the effect of various finishing processes such as bleaching and mercerising, and on the properties of cotton dyed with different dyes, is already yielding results of industrial value, and technical control of the bleaching process has been considerably improved. In a search for new uses for wool, the Wool Industries Research Association has obtained from a mixture of cellulose, leather, rubber, and wool, various products which closely resemble leather and for which uses are being explored. The Launderers' Research Association has succeeded in developing graded washing processes in which by technical control cleaner fabrics can be more rapidly obtained without increased cost of materials than by the casual processes commonly used, and methods for the economical cleansing of greasy fabrics are being evolved.

The Leather Manufacturers' Research Association has made an important contribution to public safety by the development of a method of disinfection which can be used by any tanner as a routine method of liming his goods and at the same time sterilising them against anthrax, attention is now being directed towards the development of a method by which the dry hides and skins may be disinfected at the port of entry into Great Britain. The Boot, Shoe, and Allied Trades Research Association is carrying out studies on the physical properties of leather which are intimately connected with the comfort and waterproofness of shoes. The Rubber Manufacturers' Research Association is assisting that depressed industry by discovering new uses for rubber, and particularly by studies on the use of vulcanised rubber for resisting corrosion and on the problem of securing satisfactory adhesion of rubber to metals, while the Research Association for the Cocoa, Chocolate, Sugar Confectionery, and Jam Trades has elaborated practical methods for preventing fatty bloom on chocolate and for overcoming the tendency of boiled sweets to become sticky on storage.

The above points, culled at random from the

summarised accounts of the activities of the research associations, represent in themselves an impressive and important contribution to public as well as to industrial progress. They are, however, only a fraction of the work for which the Department of Scientific and Industrial Research is responsible. Reference has already been made to the National Physical Laboratory, a feature of the work of which is the assistance rendered to industry by investigations and routine tests for industrial firms. Each of the seven main divisions of the Laboratory—Physics, Electricity, Metrology, Engineering, Metallurgy, Aerodynamics, and the William Froude Laboratory—is making valuable contributions to industrial progress, sometimes directly, sometimes through work carried out for a research board or association. The erection of equipment for the production of artificial fogs has much facilitated work in progress for the Atmospheric Pollution Research Committee, while the Engineering Department has carried out for the Ministry of Transport work of such obvious practical importance as tests on concrete for roads, skidding experiments with a motor-cycle and side-car and with a small model four-wheeled vehicle. The investigations on the spinning of aeroplanes, air-screw pressure and flutter, flutter of aeroplane tails, the wind resistance of ships, as well as the influence of waves on resistance, propulsion, and pitching, are only a few of the further ways in which the work of the National Physical Laboratory reflects on the question of transport and safety which is so vital in modern society.

The work carried out under the Fuel Research Board has received a considerable amount of attention recently, particularly that concerned with the hydrogenation of coal. Equally important, however, are the physical and chemical survey of the national coal resources, the investigations on carbonisation, gas production, treatment of tar to produce satisfactory fuel oils and motor spirit, coal-cleaning, and heat transfer which are proceeding quietly but steadily.

Transport, fuel, and atmospheric pollution are only three of the fields in which the work of the Department impinges broadly on daily life and needs. Important undertakings like the Southampton Docks and Water Supply, London Underground Railways, Battersea Power Station, the Millwall Drainage Tunnel, the Haweswater Reservoir Scheme, the Thames Tunnel, and the Mid-Scottish Ship Canal have resorted to the Geological Survey for information during the year.

The Building Research Board continues its efforts to substitute a science of building for empirical methods of trial and error, and has succeeded in formulating generalisations for the laying of wood block floors, as well as indicating causes of failures of paint coatings in buildings. Measurements of creep in the ageing of concrete have been supplemented by observations on actual structures, and other investigations endeavour to improve the efficiency of buildings from the point of view of the user. Research on steel structures has assisted in standardising practice for the design of steel-frame

buildings and also in the application of electric welding to structural work in Great Britain. Certain of the investigations under the Forest Products Research Board are of interest in the same field, notably those concerned with specifications for building timber, wood preservative, and the study of dry rot and the death-watch beetle, while metallurgical research on the effect of corrosive media on boiler steel under relatively severe plastic deformation is obviously of interest in regard to public as well as industrial safety.

Similarly, the public and industrial interests of work carried out under the Water Pollution Research Board are not easily separated. The investigation on beet sugar factories' effluent had already led to modifications in the factory processes, the cost of which was at least counterbalanced by resultant economies in other directions. Laboratory work has now indicated that certain organisms are of special value in the purification of waste waters containing sugar, while the surveys of the river Tees and the Firth of Tay have indicated that polluting matter is not readily carried out to sea unless it is in the surface layer when it reaches the estuary. The scarcity of living organisms in the middle section of the Tees estuary cannot be attributed solely to pollution, and observations are being recorded on the migration of salmon and sea trout smolts. Some of the work on water pollution is linked up with investigations at the Chemical Research Laboratory, where it has been found that base-exchange materials remove from water traces of undesirable metals such as lead, copper, and zinc, which may be present in solution. Apart from its other investigations on corrosion, low-temperature tar, etc., the Chemical Research Laboratory has also been responsible for investigations on a series of fluorene derivatives containing arsenic and a new group of arsenicals analogous to trypanamide, both of which possess promising therapeutic activity.

Much valuable radio research has been carried out on the propagation of waves, aerials for transmission and reception, direction finding, and atmospheric, the significance of which is obvious to an increasingly large proportion of the population, while lubrication, illumination, and dental research, and, until April 1, 1931, the preservation and restoration of exhibits in the British Museum are among other activities of the Department the public significance of which is obvious. In regard to the latter work, which has now been transferred to the Trustees of the British Museum, mention may be made of services rendered at the Persian Art Exhibition, the use of chloramine-T for removing stains produced by mould and mildew in water-colour drawings and engravings, as well as the use of vinyl acetate for strengthening porous and friable material.

No summary, however brief, of the work of the Department is complete without reference to the work of the Food Investigation Board. Some account of the investigations of this Board has recently appeared in our columns, and it is unnecessary to add more than that the work of the Food Investigation Board represents the only

serious scientific study of the possibilities of low temperature gas-storage of fresh fruit and vegetables, and its success has already led to the erection of several commercial gas-stores for apples. Problems connected with the corrosion of cans by fruit juices and syrups have been surveyed, the transport and storage of bacon and pork as well as freezing and storage of meat and eggs are all receiving attention, while it has also been found that temperatures below  $0^{\circ}\text{F}$  are required for the storage of brine-frozen haddock. Other investigations at the Torrey Research Station are concerned with the design of

plant for the extraction of liver oil on steam-trawlers at sea and for the smoke-curing of fish, and it is not too much to claim that the national importance of the food investigations of the Department alone justify a large proportion of the whole expenditure on scientific and industrial research. Certain it is that few fractions of the national income are more wisely administered or expended with more profit both to society and to industry than the comparatively small sums which are entrusted by Parliament to the Department of Scientific and Industrial Research.

### Obituary

#### PROF R STENHOUSE WILLIAMS

PROF R STENHOUSE WILLIAMS, first director of the National Institute for Research in Dairying, who died on Feb 2 at the age of sixty years, went to Reading in 1912 equipped for the study of the dairying industry with a thorough knowledge of bacteriology, a science for which he had the greatest reverence and the status of which he jealously guarded. His profession as a physician and his academic career assisted him in the broad outlook which he brought to bear on the industry of his adoption. As a medical man he realised the importance of the nation's milk supply, as a bacteriologist he was scandalised by the conditions which were associated with milk production, and as a teacher he deplored the apathy and ignorance which tolerated such conditions.

With a characteristic thoroughness, Prof Stenhouse Williams set himself to study the position, and brought his science and personal observation to bear on every stage in the passage of milk from the cow to the consumer. He did not content himself merely with working out scientific technique for the production of a clean and safe milk supply, he also realised the difficulties of the practical side and the necessity of keeping down the cost of production. It was here that his special gift of inspiring efficient social service came into full play. He became the friend of the farmer and of the milk distributor, inspiring in all with whom he came in contact the right mentality for their especial duties. Every grave error in the handling of milk he treated as a mistake which could be overcome by care and co-operation, and no hour of the day was too early or too late for him to give help and advice in cow byre or distributing centre.

Prof Stenhouse Williams realised the necessity for technical education in all branches of the milk industry, and was active in the organisation of lectures, classes, and competitions with the view of increasing both the knowledge and efficiency of the workers. He was a man of very clear vision. He saw the foundations on which the unique nutritional value of milk is established in the order of Nature, and demonstrated on a large and convincing scale that pure and safe milk could be produced as a practical proposition. He emphasised that the work of the research institute for which he was responsible should rest on the firm foundations of

fundamental science, and he stressed the necessity for a very thorough further study of the nutritional value of milk, including all possible effects produced by heat treatment. In his fight to maintain an open door for raw milk, many have crossed swords with him who could not have realised the soundness of his contention that the present necessity of harnessing the milk supply of our large towns to any processing machine is an expedient which must not exclude the recognition of a possible clean and natural milk supply under better conditions of social service.

Great and lasting as is his achievement in this work, it was the character and personality of Stenhouse Williams himself which endeared him to those who knew him well. To others, who differed from him, he presented an uncompromising front, for he was by nature a fighter.

#### PROF W H WATKINSON

WE regret to record the death, on Feb 14, of William Henry Watkinson, emeritus professor of engineering and director of the Walker and Harrison Hughes Engineering Laboratories of the University of Liverpool.

Prof Watkinson, who was in his seventy-second year, was born at Keighley. His early training in the University of Glasgow brought him under the direction of Lord Kelvin, and, under the latter and Prof Fleeming Jenkin, he aided in the manufacture, testing, and laying of trans-Atlantic cables. For a time he held a scholarship under Kelvin, and in 1888 was put in charge of the Engineering Department of the Central Science School, Sheffield. In 1893 he was appointed to the chair of engineering in the Glasgow and West of Scotland Technical College.

In 1905, Watkinson was appointed to the chair of engineering in Liverpool, and was largely responsible for the growth of that school. His efforts for engineering resulted in the building and equipment, in 1912, of the beautiful laboratories which he later directed. He was also instrumental in the foundation of the chairs of naval architecture and thermodynamics in Liverpool.

Watkinson's personal investigations related in particular to pioneer work on gas engines and air

heaters and superheaters for boilers. For twenty-one years he was a member of council of the Liverpool Engineering Society, and for a time served as president to the Society. He served also as chairman of the North-Western Branch of the Institution of Mechanical Engineers and as a member of its Council.

Watkinson will long be remembered for the kindness of his disposition and for the ceaseless efforts which he made to further the welfare of his School and the interests of his pupils.

WE regret to announce the following deaths.

Dr W. D. Dye, F.R.S., principal assistant in the Electrical Standards Department of the

National Physical Laboratory, on Feb. 18, aged forty-four years.

Dr James Mercer, F.R.S., fellow and lecturer in mathematics at Christ's College, Cambridge, on Feb. 21, aged forty-nine years.

Sir William Somerville, K.B.E., honorary fellow of St John's College, Oxford, and emeritus professor of rural economy in the University of Oxford, on Feb. 17, aged seventy-one years.

Prof J. A. Udden, director of the University of Texas Bureau of Economic Geology, known for his work in the development of the mineral resources of Texas, on Jan. 5, aged seventy-three years.

Prof Ernest Wilson, emeritus professor of electrical engineering at King's College, London, on Feb. 17, aged sixty-eight years.

### News and Views

#### Centenary of Jean François Champollion

ON March 4 occurs the centenary of the death of Jean François Champollion, the distinguished French Egyptologist, who first deciphered the hieroglyphics. Born on Dec. 23, 1790, at Figeac, in the Department of Lot, he was the younger brother of Jean Jacques Champollion-Figeac (1788-1867), the archaeologist and librarian. He was sent by his brother to school at Grenoble, and while there came under the influence of the mathematician Fourier, who had accompanied Napoleon to Egypt, and it is said that the sight of some Egyptian figures first aroused Champollion's intense interest in the East. From Grenoble he went to Paris to study Arabic and Coptic, at nineteen years of age he returned to Grenoble as a professor of history, and in 1811-14 published his work "*L'Égypte sous les Pharaons*", covering the whole history and geography of ancient Egypt. He was afterwards robbed of his chair for a time for political reasons, but, continuing his researches, in 1822 he wrote his important memoir on the hieroglyphics, which was read to the Institute, and two years later he was enabled by Louis XVIII to visit Italy to study the collections of Egyptian antiquities. His "*Précis du système hiéroglyphique*" appeared in 1824, his catalogue of Egyptian manuscripts in the Vatican in 1826, and his account of the discovery of the hieroglyphic alphabet in 1827. The following year, with some assistants, he made an expedition to Egypt itself, and on his return in 1830 was appointed to a newly founded chair of Egyptology in the Collège de France. His death took place at the early age of forty-one years on March 4, 1832, and he was buried close to Fourier in the Père Lachaise cemetery.

#### New Physics Building at Leeds

THE new physics building of the University of Leeds, described in NATURE of Jan. 9, p. 64, was formally opened by Sir William Bragg on Feb. 18. In introducing Sir William, the vice-chancellor of the University, Sir J. B. Baillie, referred to the brilliant work carried out by Sir William Bragg during his tenure of the Cavendish chair of physics at Leeds. He also

stated that although the greater part of the £60,000 spent on the laboratory was generously contributed by the public to the general building fund, two specially generous donors specifically ear-marked their gifts for physics—Sir James Roberts and Messrs Courtaulds. Sir William Bragg, in his address, discussed the change of attitude on the part of the general public during the past eighty years or so towards the work of the physical laboratory. There has been increased interest in the progress of natural knowledge and also in its application to everyday needs. At one time private benefactors alone founded and maintained learned institutions, nowadays, such institutions receive public grants. John Citizen has realised the value of the advance of knowledge by experiment, and is willing to pay for it. Sir William would now like to see him in the laboratory itself, and suggested that every opportunity should be taken "to demonstrate visually to John Citizen the slow unfolding of Nature's laws by patient research, the discovery of unsuspected beauties of order and adaptation, the origin of the new conception of the universe, and, not least, the skilful handling of new knowledge for the service and delight of man." Prof R. Whiddington, in moving a vote of thanks to Sir William Bragg, said he felt sure the new building would for a long time function efficiently and, by virtue of its internal conveniences and appearance, induce the right atmosphere for teaching and research. He felt one regret in leaving the old building to its fate: there was a hallowed corner where his famous predecessor, Sir William Bragg, had made historic experiments—this place would soon be covered by the Brotherton Library. He felt sure that it would be possible to mark the spot suitably when the library is built.

#### Presentation to Prof. W. W. Watts, F.R.S.

ON Feb. 3, a representative gathering of past and present members of staff of the Geological Department of the Imperial College of Science met for the purpose of presenting Prof. W. W. Watts with his portrait, painted by Sir William Rothenstein. A medal, to be known as the Watts Medal, was also struck as an additional mark of the occasion. This

medal, executed by Mr Percy Metcalfe, is to be awarded annually to the best student in geology in his final year, but the first copy was presented to Mrs Watts. In making the presentations on behalf of the fifty members of staff who have served in the Department of Geology during the last twenty-five years, Prof P G H Boswell recalled Prof Watts's high distinction as an original investigator, and referred to the great influence he has exercised on British geology in his time. Geology generally has benefited by Prof Watts's well-known capacity for organisation and administration and by his genius as a teacher, in which field he is *felicissime princeps*. Prof Watts, in returning thanks, acknowledged the encouragement and help he had received from his teachers and associates, and took the opportunity of announcing the establishment of a prize-fund in memory of his predecessor, Prof J W Judd. In a characteristically happy speech, he charged his old students and staff with having used, when they turned their microscopes on him, only low powers and parallel nicols, so that they saw a gorgeous display of colour, but failed to observe his angle of extinction.

#### Geology in International Affairs

ON Feb 18, Prof H. H. Read, George Herdman professor of geology in the University of Liverpool, delivered his inaugural address. In discussing certain aspects of geology, both national and international, Prof Read stated that the importance of mineral deposits in national and international affairs arises from three main factors, namely, the irregular distribution of minerals among the nations, their character as irreplaceable wasting assets, and the gigantic acceleration in their consumption. A survey of the present and future mineral position shows that the British Empire, provided it remains a unit of intelligent type, and the United States are together overwhelmingly dominant. The Empire's chief lack is petroleum, a circumstance giving added importance to the production of oil from coal. The dominance of these two units leads to the consideration of schemes for the prevention of war, similar to those suggested by Sir Thomas Holland. A mineral sanction, or an agreement by the United States and the British Empire not to export key minerals to disturbers of the peace would prevent, stop, or at least limit, war.

#### Blind Reading Print by Sound

SEVERAL devices have been invented with the view of enabling the blind to read ordinary print instead of Braille. As mentioned in NATURE of Jan 9, p 52, the 'optophone' was invented by Dr Fournier d'Albe and the 'phonopticon' by Prof F C Browne. These two instruments convert ordinary type directly into sound signals, but according to Dr Ernest Whitfield, of the National Institute for the Blind, London, neither is in use in any institution for the blind. We understand also that there is no alphabet requiring more training than one which converts printing into sound. The 'photoelectrograph' of MM Thomas and Conland, as announced in our note, involves touch; but since the Braille type part of the machine

would necessitate the printing of books in special type, it would involve a cost beyond the reach of the average blind person. We have also been reminded of other instruments for aiding the blind, including the 'optograph' of Dr J Butler Burke, which involves the use of a photoelectric cell to convert typewritten or printed matter into Braille, and also sets up type automatically, this instrument was exhibited at the Exhibition of Inventions in October 1929. Another instrument is the 'visagraph' invented by Mr Robert E Naumburg, of Cambridge, Mass. This latter involves touch, a ray of light passing over the printed page, and the letters are reproduced in embossed type on a sheet of aluminium foil. It may be remarked that embossed 'roman type' preceded Braille, and Dr Whitfield states that it was very successful. The 'visagraph' is being used successfully in America, thus showing that ordinary type is suitable for reading by touch with reasonable speed.

#### New Political Fellowship

THE present state of party politics has given an impetus to non-party movements such as the New Political Fellowship organised by Mr A G Pape, though it is perhaps premature to predict as the ultimate outcome the formation of a centre group in our Houses of Parliament. Party politics are apparently insufficient for the present emergency. The co-operative methods advocated by the New Political Fellowship, based on a definite planning of national and international life which is determined by an impartial study of the facts, not by political prejudice, are much more in harmony with the methods and outlook of scientific workers. The Fellowship, which already has a basis in some thirty countries, claims to break with useless traditions, and to substitute for the narrow, national jealousies a broad outlook and a spirit of co-operation which will enable existing international machinery, such as the League of Nations, the International Labour Office, etc., to function smoothly. However idealistic certain of the points in this policy may appear, they undoubtedly spring from the conviction that leadership must be based primarily on knowledge and no longer on prejudice or vested interests. In this the Fellowship can justly ask the support of men of science, without whose support its efforts indeed are likely to be largely sterile. It is only the solutions reached under the guidance of the calm impartial spirit of science that will have permanent value and authority in the era of co-operation which the Fellowship seeks to promote.

#### Charles II. Exhibition in London

THE period of Charles II is so intimately connected with the beginnings of some of our principal scientific institutions that it is satisfactory to record that the Royal Society, the Greenwich Observatory, the Old Ashmolean Museum, Chelsea Hospital, and Hudson's Bay Company, all dating from his reign, should be joining in contributing contemporary exhibits to the Loan Exhibition now being held at 22 Grosvenor Place, London. The scientific exhibits include the

reflecting telescope of Isaac Newton, a full-sized model of Hooke and Boyle's pneumatic engine or air-pump, Sutton's 16-inch planisphere, quadrants, and the adding machine invented by Sir Samuel Morland and presented to Charles II in 1666, from the Lewis Evans Collection in the Old Ashmolean at Oxford. Viscount Knutsford is showing his interesting screw-barrel microscope and 6-foot vellum-draw telescope by William Longland. The Royal Society has sent portraits of Sir Isaac Newton, Pepys, Evelyn, and Wren. Further attractive features are the fine clocks and watches made by Edward East with his apprentice Henry Jones, Fromanteel, Robert Seignior, and Joseph Knubb. The medical and surgical practice of the time is rather inadequately represented by a barber-surgeon's bowl and several drug-pots, but Capt Collins's "Coasting Pilot", exhibited by the Lords of the Admiralty, reminds us that the first hydrographic survey of the British Isles was also a product of the reign of Charles II. The exhibits are well arranged, and, not being crowded, can be well seen.

#### New Pyramid at Giza

THE discovery of a fourth pyramid at Giza, as reported in the *Times* of Feb. 18 and subsequent issues, is likely to provide Egyptologists with a historical puzzle, as well as presenting some peculiar and interesting features in itself. The method of construction would appear to be unusual, for it is said that the southern face, which looks on the valley and is much weathered, is cut out of the sandstone. Another remarkable feature is the enormous granite slabs lining the passage which leads to the interior of the pyramid, and equally interesting are the two windows facing east, which open from the entrance chamber. These, it is suggested, may be connected with the enhanced influence of sun-worship usually attributed to the fifth dynasty. The most striking feature, however, is the fact that the names and titles of the owner of the large chamber cut out of the rock on the south-east of the pyramid show that it belonged to Queen Khent Kawes, "King of Lower and Upper Egypt". The name is not enclosed in the usual cartouche, but is ensigned with a royal uræus. This title is not known to have been applied to any other queen of the Old Kingdom. The official communique suggests that, while not the actual ruler of Egypt, she may have been regent during her son's minority. It goes on to point out that it is possible that she may have been connected by birth with the fourth dynasty; but that otherwise it is singular that a pyramid should have been erected for her at Giza at the time of the fifth dynasty, which resided at Abusir.

#### Gallium, a Commercial Product

ALTHOUGH the presence of the metal gallium has been detected in a great variety of minerals, it occurs in such minute amount even in zincblende, which is its chief source, and its isolation is so laborious, that until quite recently only very small quantities were available. The *Chemiker-Zeitung* for Jan. 2 announces that the Vereinigte Chemische Fabriken at Leopoldschall, Stassfurt, manufacturers of the rare element

rhenum, have succeeded, after lengthy experimental trials, in isolating gallium by a method which enables them to produce the metal at one-twentieth of its former cost, which a year ago stood at about 175 gold marks per gram. Thus the way to the commercial development of this remarkable metal is at last opened.

CONSIDERABLE attention has already been given to the properties of gallium, chiefly on account of the long thermal range of stability of its liquid phase. Thus the pure metal melts at about 30° C and boils at a temperature above 2000° C. It has therefore been used for filling quartz thermometers for registering temperatures above 500° C. Some of these have already been sent to the Physikalisch-Technische Reichsanstalt for standardisation. Gallium can also be used to replace mercury in vapour arc-lamps for use in analytical work. Indeed, its application in this direction should lead to important results, on account of the wide range in frequency in the lines of its spectrum, which extend from the ultra-violet to well into the red region. It has also been used in the form of alloys with other metals to replace the dental amalgams, which are said to have produced some harmful results. Satisfactory results from gallium alloys have been reported. Gallium and some of its alloys can also be used for the production of special optical mirrors, and no doubt many other applications will be found now that the metal has become an article of commerce.

#### Earth Pressures

At the Friday evening discourse at the Royal Institution on Feb. 19, Prof. C. F. Jenkin discussed the mechanics of shifting sand. Prof. Jenkin explained why experiments intended to measure the pressure exerted by granular material, such as sand, fail, and showed that the failure is due to arching, a necessary consequence of the property of dilatancy, discovered by Osborn Reynolds. The latest design of apparatus for measuring the forces on a retaining wall was shown, and the results of a test made with it were described. With this apparatus the old earth pressure theories have been tested and the truth in them separated from the error. As a result, a revised wedge theory has been formulated. The apparatus was shown to be capable of measuring the forces not only on plane walls, of any batter, but also on stepped walls and on L-shaped walls, and also of measuring the forces under water. Finally, by an ingenious device, a wall of sand has been tested and the true friction angle between two sand faces measured. The reaction, that is, the force exerted by the wall on the sand, was described and its importance illustrated by an account of the partial failure of a great weir in Australia. The apparatus described can only deal with one-quarter of the whole problem of earth pressures; it cannot measure the forces under a foundation, and it cannot measure either horizontal or vertical forces exerted by clay.

#### International Co-ordination of Locust Research

SOME time ago the Imperial Institute of Entomology in London organised, with the financial support of the

Empire Marketing Board, special investigations on the distribution, breeding areas, migration routes, ecology, and bionomics of locusts in tropical Africa and Asia. An appeal was made by the British Government to the governments of other countries interested in the locust problem to help in these studies, and the Italian Government came forward with a suggestion to call together a meeting of experts to discuss the ways and means for a unified attack of the problem. The meeting, in which British, Italian, and French experts participated, took place in September last in Rome, and its resolutions, which have just been published, constitute the first step towards an effort to solve the locust problem on an international scale. The meeting expressed a definite opinion that the best and most economical method of preventing the ravages of locusts consists in the discovery of permanent breeding areas, and in the study of ecological conditions which lead to the outbreaks and invasions of cultivated areas.

SINCE in their migrations locusts do not respect political boundaries, the necessity of centralising all research on locusts in one institution was stressed at the meeting in Rome, and it was recommended to all the governments concerned that the Imperial Institute of Entomology should be recognised as the international centre of locust investigations. This decision has since been accepted by the Italian and French authorities. All current information on the appearances, breeding, and migrations of locusts are to be submitted periodically to the Institute, which will co-ordinate the data for the whole area of distribution of each locust species and study them in order to throw light on the factors governing the outbreaks and the main lines of migrations. All governments not represented at the Rome meeting, but interested in the locust problem, will be invited to co-operate with the central Institute, and annual meetings of experts will be arranged to discuss the progress made in each country in the study of locusts, and the programmes of future work. The next meeting of this kind is planned to take place in Paris at the time of the Fifth International Entomological Congress in July.

#### The Lapel Microphone

At public meetings and at lectures, the microphone and loud speaker is often a great boon to both the speaker, who speaks practically in his natural voice, and to the audience, who hear him clearly. There are some, however, who forget that they are addressing a stationary microphone and move about freely, with the result that sometimes they can scarcely be heard. To get over this difficulty, the Bell Telephone Company has invented the lapel microphone, a description of which is given in its *Record* for January. The microphone is only about an inch in diameter and weighs one and one-half ounces. A thirty-foot length of flexible cord provides the connexion to the amplifier of the public address system. The diaphragm is made of thin aluminium in the shape of a cone of sufficient stiffness to cause it to vibrate as a unit throughout the required frequency range. A rubber covering for the microphone eliminates the disturbing noise which would otherwise result from rubbing against the

speaker's clothing, or would be picked up through the clip which is provided for attaching it to the clothing. The best place to attach the clip is to the lapel of the speaker's coat. This device has been used very successfully in large auditoriums in America. It should prove useful to speakers who depend on gestures for effective delivery or who need to turn to explain lantern slides or use a blackboard.

#### Publications of the American Physical Society

COMMENCING with the first issue for January of this year, the *Physical Review* is publishing the titles of papers on physics that are appearing in a number of other journals. The value of this innovation is enhanced by the fact that arrangements have been concluded whereby many of these will furnish advance proofs of their tables of contents. The first list is fairly comprehensive, although one notices the omission of the *Proceedings of the Cambridge Philosophical Society*, and of a few others, which may, however, be rectified later. The American journals include, amongst others, the *Journals* of the Acoustical and Optical Societies, the *Journal of Rheology*, the *Review of Scientific Instruments* and *Physics*. This is the fifth comparatively recent change in the publications of the American Physical Society and follows the appearance of the *Physical Review* twice every month in place of twelve times in a year, the addition of a section in this for "Letters to the Editor", and the publication of the two new periodicals *Physics* and *Reviews of Modern Physics*.

#### Comité International d'Histoire des Sciences

THE fourth annual meeting of this Society, the second international congress of which, it will be remembered, was held in London last July, is to take place in Paris on May 13-16. The Council of the Society is convinced that one of the most important tasks confronting the historian of science is to study the development under Arabic influence during the period of its dominance, say from the date of the Mussulman conquest until the beginning of the sixteenth century. To promote and organise this study, the scientific sessions, as distinct from the business sessions which are confined to members, will be devoted exclusively to papers and discussions on Arabic science. In these sessions all those who are interested, members or not, are invited to take part and to submit papers. There will be five sessions, devoted to mathematics, alchemy, astronomy and physics, geography and cartography, and medicine respectively. The meeting will take place at the headquarters of the Society, Hôtel de Nevers, 12 rue Colbert, Paris, 2e, the permanent secretary, M. Aldo Mieli, will be pleased to furnish a programme and further details.

#### Progress of Agricultural Research

THE sixth of the series of annual summaries of scientific and economic research work in agriculture has been published by the Royal Agricultural Society of England, entitled "Agricultural Research in 1930". The survey which the volume contains is not limited to work done in Great Britain, but includes reference to the activities of experimental stations in all parts of the world, in so far as they have a bearing upon the

problems of British agriculture. The present volume follows upon the lines of the previous issues as to the seven departments of research covered, and each of these sections is compiled by an acknowledged authority on the subject. The volumes are issued free to members of the Society upon application to the Secretary, 16 Bedford Square, London, W C 1, and at a nominal charge of 1s 3d, including postage, to the general public. The Research Committee, under the direction of which they are prepared, is desirous that the information contained in them should be drawn upon freely by county agricultural advisory officers and by the Press, so that it may receive a wide publicity.

#### Economic Research in Australia

THE *Journal of the Council for Scientific and Industrial Research* of the Commonwealth of Australia contains reports of many investigations of pressing economic problems, to some of which reference will be made under our Research Items. Here we simply wish to congratulate the Council upon the completion of its new Animal Health Laboratory, the result of a sum of £20,000 given by Mr F. D. McMaster for that purpose. The Laboratory is placed within the grounds of the University of Sydney, alongside the buildings of the Veterinary Department, and the closest contact is maintained between the two staffs. The work already in progress in the building relates to internal parasites of sheep, including nutritional aspects of this problem, contagious mammites, certain aspects of foot-rot of sheep, and other problems. It is obvious that the Laboratory is in a position to play an important part in the study of those aspects of the Australian pastoral industry which are in great need of solution if the industry is to flourish. The building is of brick, with red-tiled roof, measures 155 feet by 43 feet, is two-storied, and has been constructed so that other stories or rooms may be added with the minimum of disturbance.

#### New Chief Entomologist at Rothamsted

THE position of Chief Entomologist at the Rothamsted Experimental Station, rendered vacant by the appointment of Dr A. D. Inms as head of the new Department of Entomology at Cambridge, is to be filled by Dr C. B. Williams, lecturer in agricultural and forest zoology, University of Edinburgh. Dr Williams has had a distinguished career as entomologist in various parts of the British Empire; he received his training at Cambridge and then at the John Innes Horticultural Institution, Merton. After a period of travel in Canada and the United States, he was appointed to the Department of Agriculture of Trinidad, in charge of frog-hopper investigations, where he stayed for five years. He then became sub-director and afterwards director of the Entomological Section, Ministry of Agriculture, Egypt, and after six years' service was appointed entomologist to the East African Agricultural Research Station, Amani, Tanganyika. He is shortly proceeding to the United States of America to give a course of lectures at the Agricultural Department of the University of Minnesota, and will take up his duties at the Rothamsted Experimental Station on July 1.

#### Fellowship of African Research

IT is announced that a Rockefeller fellowship for research work in Africa has been awarded to Miss L. C. Mair. Miss Mair has worked with Prof. B. Malinowski at the London School of Economics as research assistant. She has already left for Uganda, where she will study native social institutions with special reference to the changes which have been brought about by European settlement. The comparatively highly organised character of the social institutions of the Baganda before they came into contact with Europeans, and the readiness the people have shown in adapting themselves in certain directions to European ideas, should make this a fruitful and particularly instructive field of inquiry, especially if opportunity should arise for comparison with other areas of East Africa in which contact with European civilisation has been neither so prolonged nor so intense.

#### The Cuba Earthquake of Feb. 3

ACCORDING to the *Wire Reports* for Feb. 3 and 4 issued by Science Service, the epicentre of the Cuba earthquake of Feb. 3 lay in about lat. 19° 5' N, long. 76° 5' W, or about thirty miles from Santiago, on the northern edge of the Bartlett Deep. At the time of the earthquake, Prof. S. Taber was in Santiago, studying the seismology of the district. He has found faults near Santiago so fresh that gullies made by rain have not yet crossed them. The U.S. submarine *S-48*, carrying an international scientific expedition, left on Feb. 4 to study the depths and changes of depth in the Bartlett Deep, an inquiry that may add to our knowledge of the origin of the recent earthquake.

#### Announcements

THE thirty-seventh annual congress of the South-Eastern Union of Scientific Societies will be held in London, at the Civil Service Commission, Burlington House, W.1, by permission of H.M. Office of Works, on June 1-4, under the presidency of Dr R. E. Mortimer Wheeler, Keeper of the London Museum.

ON March 7, the Hon. Henry McLaren, president of the Royal Horticultural Society, will unveil a plaque at Messrs. Hatchards, 187 Piccadilly, London, to commemorate the foundation of the Horticultural Society of London at Messrs. Hatchards on March 7, 1804. The Society received its royal charter on April 7, 1809, becoming the Royal Horticultural Society.

AT the annual general meeting of the Quekett Microscopical Club, held on Feb. 9, the following officers and new members of the committee were elected: *President*—J. Milton Offord, *Vice-Presidents*—Dr G. H. Rodman, J. Wilson, C. D. Soar, and J. Ramsbottom, *Hon. Treasurer*—C. H. Bestow, *Hon. Secretary*—W. S. Warton, *Hon. Reporter*—A. Morley Jones, *Hon. Librarian*—C. H. Caffyn, *Hon. Curator*—C. D. Sidwell, *Hon. Editor*—W. S. Warton, *New Members of Committee*—J. T. Holder, C. H. Oakden, H. C. Payne, J. Richardson, W. P. Sollas, and Dr C. Tierney.

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

## Possible Existence of a Neutron

It has been shown by Bothe and others that beryllium when bombarded by  $\alpha$ -particles of polonium emits a radiation of great penetrating power, which has an absorption coefficient in lead of about  $0.3 \text{ (cm)}^{-1}$ . Recently Mme Curie-Joliot and M Joliot found, when measuring the ionisation produced by this beryllium radiation in a vessel with a thin window, that the ionisation increased when matter containing hydrogen was placed in front of the window. The effect appeared to be due to the ejection of protons with velocities up to a maximum of nearly  $3 \times 10^9 \text{ cm per sec}$ . They suggested that the transference of energy to the proton was by a process similar to the Compton effect, and estimated that the beryllium radiation had a quantum energy of  $50 \times 10^6 \text{ electron volts}$ .

I have made some experiments using the valve counter to examine the properties of this radiation excited in beryllium. The valve counter consists of a small ionisation chamber connected to an amplifier, and the sudden production of ions by the entry of a particle, such as a proton or  $\alpha$ -particle, is recorded by the deflexion of an oscillograph. These experiments have shown that the radiation ejects particles from hydrogen, helium, lithium, beryllium, carbon, air, and argon. The particles ejected from hydrogen behave, as regards range and ionising power, like protons with speeds up to about  $3.2 \times 10^9 \text{ cm per sec}$ . The particles from the other elements have a large ionising power, and appear to be in each case recoil atoms of the elements.

If we ascribe the ejection of the proton to a Compton recoil from a quantum of  $52 \times 10^6 \text{ electron volts}$ , then the nitrogen recoil atom arising by a similar process should have an energy not greater than about 400,000 volts, should produce not more than about 10,000 ions, and have a range in air at N.T.P. of about 1.3 mm. Actually, some of the recoil atoms in nitrogen produce at least 30,000 ions. In collaboration with Dr Feather, I have observed the recoil atoms in an expansion chamber, and their range, estimated visually, was sometimes as much as 3 mm at N.T.P.

These results, and others I have obtained in the course of the work, are very difficult to explain on the assumption that the radiation from beryllium is a quantum radiation, if energy and momentum are to be conserved in the collisions. The difficulties disappear, however, if it be assumed that the radiation consists of particles of mass 1 and charge 0, or neutrons. The capture of the  $\alpha$ -particle by the  $\text{Be}^9$  nucleus may be supposed to result in the formation of a  $\text{C}^{12}$  nucleus and the emission of the neutron. From the energy relations of this process the velocity of the neutron emitted in the forward direction may well be about  $3 \times 10^9 \text{ cm per sec}$ . The collisions of this neutron with the atoms through which it passes give rise to the recoil atoms, and the observed energies of the recoil atoms are in fair agreement with this view. Moreover, I have observed that the protons ejected from hydrogen by the radiation emitted in the opposite direction to that of the exciting  $\alpha$ -particle appear to have a much smaller range than those ejected by the forward radiation.

This again receives a simple explanation on the neutron hypothesis.

If it be supposed that the radiation consists of quanta, then the capture of the  $\alpha$ -particle by the  $\text{Be}^9$  nucleus will form a  $\text{C}^{13}$  nucleus. The mass defect of  $\text{C}^{13}$  is known with sufficient accuracy to show that the energy of the quantum emitted in this process cannot be greater than about  $14 \times 10^6 \text{ volts}$ . It is difficult to make such a quantum responsible for the effects observed.

It is to be expected that many of the effects of a neutron in passing through matter should resemble those of a quantum of high energy, and it is not easy to reach the final decision between the two hypotheses. Up to the present, all the evidence is in favour of the neutron, while the quantum hypothesis can only be upheld if the conservation of energy and momentum be relinquished at some point.

J CHADWICK

Cavendish Laboratory,  
Cambridge, Feb 17

## The Oldoway Human Skeleton

A LETTER appeared in NATURE of Oct 24, 1931, signed by Messrs Leakey, Hopwood, and Reck, in which, among other conclusions, it is stated that "there is no possible doubt that the human skeleton came from Bed No 2 and not from Bed No 4". This must be taken to mean that the skeleton is to be considered as a natural deposit in Bed No 2, which is overlaid by the later beds Nos 3 and 4, and that all consideration of human interment is ruled out.

If this be true, it is a most unusual occurrence. The skeleton, which is of modern type, with filed teeth, was found completely articulated down even to the phalanges, and in a position of extraordinary contraction. Complete mammalian skeletons of any age are, as field palaeontologists know, of great rarity. When they occur, their perfection can usually be explained as the result of sudden death and immediate covering by volcanic dust. Many of the more or less perfect skeletons which may be seen in museums have been rearticulated from bones found somewhat scattered as the result of death from floods, or in the neighbourhood of drying water-holes. We know of no case of a perfect articulated skeleton being found in company with such broken and scattered remains as appear to be abundant at Oldoway. Either the skeletons are all complete, as in the *Stenomylus* quarry at Sioux City, Nebraska, or are all scattered and broken in various degrees, as in ordinary bone beds. The probability, therefore, that the Oldoway skeleton represents an artificial burial is thus one that will occur to palaeontologists.

The skeleton was exhumed in 1913, and published photographs show that the excavation made for its disinterment was extensive. It is, therefore, very difficult to believe that in 1931 there can be reliable evidence left at the site as to the conditions under which it was deposited. If naturally deposited in Bed No 2, the skeleton is of the highest possible importance, because it would be of pre-Mousterian age, and would be in the company of *Pithecanthropus* and the Pittedown, Heidelberg, and Peking men, all of whose remains are fragmentary to the last degree. Of the few other human remains for which such antiquity is claimed, the Galley Hill skeleton and the Ipswich skeleton are, or apparently were, complete. The first of these was never seen *in situ* by any trained observer, and the latter has, we believe, been withdrawn by its discoverer. The other fragments, found long ago, are entirely without satisfactory evidence as to their mode of occurrence.

We are, therefore, forced to the conclusion that the Oldoway man reached the position in which he was found by an artificial and probably a relatively recent burial, and should be glad to hear from Messrs Leakey, Hopwood, and Reck on what grounds they have based their statement that there is no possible doubt that the human skeleton came from Bed No 2

### Segregation of Cementite from Austenite

THE formation of new phases in alloys by precipitation from solid solutions has recently been studied extensively<sup>1</sup>. These studies have given experimental evidence indicating that when a precipitate forms as plates within a crystalline grain, the crystallographic plane to which the plate lies parallel is determined, not only by the lattice structure of the parent solid solution, but also by the lattice structure of the precipitate.

Recently Hanemann and Schroder<sup>2</sup> have stated that the external form of the precipitate is determined only by conditions of diffusion, which, in turn, are determined only by the lattice structure of the parent solid solution. In proof of this contention, they state that  $\text{Fe}_3\text{C}$  (cementite) precipitating in alloys of iron and carbon between 0.9 and 1.7 per cent carbon from the solid solution of carbon in gamma iron (austenite) forms in plates parallel to octahedral and cube planes in the austenite, a behaviour identical with that shown by 'pure' iron (ferrite) precipitating in alloys with less carbon (0–0.9 per cent) from the same parent solid solution, though the crystal structures of the two precipitating phases are radically different.

This problem has been studied at the Naval Research Laboratory, with results different from those of Hanemann and Schroder. The analysis of the cementite structure is more difficult than that of other Widmanstätten figures. Iron-carbon alloys suffer a eutectoid inversion at  $720^\circ$ , and for this reason the matrix in which cementite plates are found embedded within each cell at room temperature is pearlite, with no residuum of the original austenite lattice. For this reason, the positions of the cementite plates cannot be directly compared with the positions of the crystallographic planes in the original austenite parallel to which the cementite plates form. Indirect methods, however, have proved useful.

A sample with 1.4 per cent carbon exhibiting several very large austenite cells—some a centimetre in diameter—and showing unusually large and well-formed cementite plates, was polished on three faces approximately at right angles in such a way that a chosen cell lay at a corner, extending well along each of the three sides. The angular positions in space taken by the individual cementite plates that could be seen to extend from one face around a  $90^\circ$  edge to another face were determined by measuring the angles formed by each separate plate trace with the edge. By a series of eight regrinding and repolishing operations, ninety-seven needles were successfully traced around an edge and measured. The angular positions in space of these plates were then plotted stereographically, as shown in Fig. 1, in which the plane of the projection is one of the polished faces, the normals to the cementite plates appearing as dots. It may be seen in this plot that the stereographic points group

themselves in three circles. Symmetry considerations suggest that these points are grouped around three mutually perpendicular axes, and an approximation of the centre of each of the circles—the approximate centres of gravity determined by intersecting stereographic great circles—should give the approxi-

FIG 1

mate positions of these three axes. It was found that positions obtained in this way (the small crosses in Fig. 1) could be stereographically rotated into  $[100]$  directions of a standard cubic projection with surprising accuracy. Fig. 2 shows the result of this rotation, with  $[100]$  directions plotted as squares.

FIG 2

It seems quite certain that the  $[100]$  directions obtained in this way truly represent the  $[100]$  directions in the original austenite lattice—or equivalently, the stereographic projections of the  $(100)$  planes, cubic symmetry permits no other interpretation. The exact grouping of the projections of the cementite plates around these  $(100)$  positions, however, is difficult to interpret. A comparison with a standard projection shows that no one form of plane in the austenite lattice can explain the projections of all the cementite plates, for they scatter rather irregularly

on the circle about the (100) positions. When all the points shown in Fig 2 are stereographically rotated into one quadrant, some slight evidence of grouping centring around the projections of the (722) and (521) planes becomes evident, but this grouping is not sufficient to permit a choice of the austenite planes to which the cementite plates lie parallel.

However, it is clear that the cementite plates do not lie parallel to (111) or (100) planes, and that their positions with respect to the parent austenite lattice differ fundamentally from those taken by ferrite plates. Since both ferrite and cementite form from a common phase, austenite, it seems certain that the crystal structure of the precipitate is one of the essential factors in determining the arrangement of the precipitate plates.

Other evidence besides this may be cited, however. If, as Hanemann and Schroder suggest, the formation of Widmanstätten figures—figures of segregation—in hypo- and hyper-eutectoid iron-carbon alloys is determined only by the diffusion mechanism characteristic of interstitial solid solutions such as austenite, the Widmanstätten figure obtained in iron-nickel alloys (meteorites) in which the solid solutions are purely substitutional in type should be radically different, yet the Widmanstätten figures in hypo-eutectoid iron-carbon alloys and in meteorites are crystallographically analogous. Furthermore, if diffusion conditions alone determine the type of figure, it would be expected that all Widmanstätten figures formed by precipitation from solid solutions of one basic metal would be identical in form, yet the precipitation of the  $\gamma$ -phase from the aluminum-rich terminal solid solution in the aluminum-silver system leads to the formation of plates parallel to the (111) plane, that of the  $\text{CuAl}_2$  phase from the aluminum-rich terminal solid solution in the aluminum-copper system forms plates parallel to the (100) plane, and that of the precipitate from the aluminum-rich solid solution in the aluminum-magnesium-silicon system forms plates parallel to the (100) and (110) planes. Although doubtless diffusion conditions affect the external form of a segregate from solid solutions somewhat, it seems certain that the external form taken by the precipitate and the orientation of the lattice of the precipitate are largely determined by crystallographic relationships existing between the two participating phases.

#### Beta-Rays of Radium-D

MR. H. O. W. RICHARDSON'S<sup>1</sup> most interesting investigations of the  $\beta$ -rays of radium-D induce me to make certain complementary remarks.

1. In the first place I should like to point out that the experimental results of the above-mentioned researches practically agree with the results of earlier investigations regarding the same problems. This fact is most clearly illustrated by Fig 1, which compares the results of Petrowá's<sup>2</sup> measurements (2070 measured  $\beta$ -rays) with those found by Richardson (377 measured rays).

In these diagrams the abscissæ of the maxima correspond almost exactly and the difference in the relative intensity appears to be very small, especially

if we consider Petrowá's statement that her first maximum is too low.

However, I am obliged to disagree with Richardson in the interpretation of his results. As a matter of fact, I do not agree with his supposition that the rays of 0.7 cm. ranges (in air) do not correspond with a real group of homogeneous  $\beta$ -rays. This group has not only been found by Richardson and Petrowá but also by Meitner,<sup>3</sup> and thus the existence of these rays has been proved by three different authors.

Now, if this group does really exist, it must necessarily belong to the L-electrons, as no other group of more feeble energy has been discovered in the photographs of the  $\beta$ -ray spectrum of radium-D.

If this statement proves to be exact, it is strongly opposed to some of Richardson's conclusions.

2. Hitherto it has been supposed that all the  $\beta$ -rays with ranges greater than approximately 0.7 cm.

FIG 1

are of secondary origin. This opinion does not disagree with Richardson's results. If we suppose the short  $\beta$ -rays ( $R < 0.6$  cm.) to be of tertiary (or perhaps primary) origin, it follows, from the numbers given by Richardson, that every 100 decomposed atoms emit about 115 secondary  $\beta$ -rays, which result confirms—within his limit of precision (20 per cent)—my<sup>4</sup> figures, namely, 97  $\beta$ -rays per 100 atoms.

3. As to the number of gamma-rays emitted by radium-D, the work of Gray<sup>5</sup> used by Richardson as a basis for some of his calculations appears to me to have been superseded by two more recent investigations,<sup>6,7</sup> which latter give a number of quanta of 3 per cent, against 12 per cent according to Gray.

E. STAHEL.

University of Brussels,  
Dec 1931

<sup>1</sup> H. O. W. Richardson, *Proc. Roy. Soc., A*, 133, 367, 1931.

<sup>2</sup> J. Petrowá, *Z. Phys.*, 55, 628, 1929.

<sup>3</sup> L. Meitner, *Naturwiss.*, 14, 1199, 1926.

<sup>4</sup> E. Stahel, *Z. Phys.*, 68, 1, 1931.

<sup>5</sup> J. A. Gray, *Nature*, 123, 568, 1929.

<sup>6</sup> S. Bramson, *Z. Phys.*, 66, 721, 1930.

<sup>7</sup> E. Stahel and G. J. Sizoo, *Z. Phys.*, 66, 741, 1930.

We take this opportunity of replying to the criticisms expressed in Prof. Stahel's letter printed above. Prof. Stahel has investigated<sup>1</sup> the  $\beta$ -particle emission of radium-D, using a point counter as was first accomplished by Riehl.<sup>2</sup> Through a collodion window of 0.8 mm. air equivalent thickness 0.83 particles per disintegration were registered. Stahel maintains that all these particles were photoelectrons produced by the known  $\gamma$ -ray of 47.2 ekv energy. He bases this

contention (a) on Petrová's<sup>3</sup> interpretation of a range distribution constructed from Wilson chamber observations, and (b) upon certain control experiments made upon the absorption in the counter window in his own researches<sup>1</sup>

(a) As has been suggested by one of us (N F),<sup>4</sup> Petrová's interpretation of the range distribution curve is neither self-consistent nor consistent with the results of range measurements by Wilson,<sup>5</sup> Ikeuti,<sup>6</sup> and Nuttall and Williams.<sup>7</sup> It is not self-consistent, since it is surely impossible, using any reasonable range-energy relation, to assign energies 30.9, 43.3, and 47 ekv, respectively, to homogeneous  $\beta$ -particle groups having mean ranges 0.80, 1.58, and 2.9 cm in standard air, and, from the second viewpoint the discrepancy is the more serious because in the three cases cited the energies of the photoelectron groups employed were known without ambiguity from the wave-lengths of the characteristic X-rays isolated for their production. The more recent and more extensive data of Williams<sup>8</sup> substantially confirm these earlier results, so that the only evidence in line with the interpretation of Petrová is to be found in 83 radium-D  $\beta$ -particle tracks measured by Meitner.<sup>9</sup> Knowledge of the energies in this case cannot be assumed independently of the very interpretation which is in question.

(b) Stahel examined the effect of placing a second and a third thickness of collodion in the path of the beam. He found that for every 100 particles transmitted by one, 88.5 were transmitted by two, and 76.2 by three such thicknesses of material. This almost uniform absorption apparently he regarded as indicating the absence, after passing the first absorber, of particles of less energy than that of the photoelectrons of the most intense group.

The question at issue may be put to direct numerical test. We assume the relation of Nuttall and Williams,<sup>7</sup> connecting mean range and energy, and the results of Williams<sup>8</sup> concerning transmission through thin foils. The latter, obtained by detailed analysis of  $\beta$ -particle tracks in oxygen, we assume, for rough calculation, to be directly applicable to the case of collodion, and, over the range of energies in question, we regard the form of the transmission fraction curve as independent of the initial energy of the particles. Then it is found that, for a beam consisting initially of 80 secondary electrons ( $50 L_1$ ,  $20 M_1$ ,  $10 N_1$ ) together with 10 tertiary electrons ( $M_1$ ) from the  $\gamma$ -ray of 47.2 ekv energy, 85.14 electrons are transmitted through the first absorber, 6.29 are lost in the second, and 2.24 in the third. This represents an absorption of 10 per cent in the second and third absorbers, compared with 23.8 per cent observed by Stahel. If, on the other hand, a hypothetical beam be taken such that 50 photoelectrons, secondary and tertiary, due to the above  $\gamma$ -ray, with 50 additional electrons of 12.5 ekv energy, pass through a single thickness of absorber, a parallel calculation gives its intensity, after passage through two or three such absorbers, as 88.8 or 76.0 electrons, respectively. The "additional" electrons here postulated are in the form of a group of single energy for ease in calculation only, the low value of energy assigned to them is intended merely to suggest a continuous distribution extending to very low energies. Taken together, these two calculations provide evidence against the conclusion which Stahel has drawn, but, being intended solely as illustrating the possibilities of the case, they must not be regarded as capable of yielding a solution on the evidence at hand.

The problem of the primary  $\beta$ -particle emission of radium-D, it must be admitted, is still far from a complete solution, but we hold, and our reasons

appear above, first, that in the experiments of Stahel, electrons other than those comprising the known photoelectron groups were counted, and, secondly, that the identification of these groups in the range distribution curves of Petrová is a mistaken one.

### Intensity Ratio of Fluorescent X-Ray Lines

In the course of his extensive investigations on the magnetic spectra of X-ray electrons, H. Robinson found<sup>1</sup> that the ratio of the numbers of electrons emitted from different levels of an atom is dependent upon the frequency of the exciting radiation. It was to be expected that the same dependency would be met in the behaviour of secondary X-ray lines emitted by different levels of the same atom. This expectation has already been verified qualitatively in the case of the cerium  $L$  lines by Skinner.<sup>2</sup>

In view of the importance of this effect for chemical analysis by secondary X-rays and also for different theoretical problems, we have measured the intensity ratio of silver  $L\beta_2$  and silver  $L\beta_3$  lines excited once with an effective wave-length of 2.6 Å and then with 1.3 Å. As is shown below, the variation in the wave-lengths of the exciting radiation influences the intensity ratio of the two silver lines to a very large extent.

| Effective Wave-Length in Å | Intensity Ratio of Silver $L\beta_2$ and Silver $L\beta_3$ | Change in Intensity Ratio of the two Lines |
|----------------------------|------------------------------------------------------------|--------------------------------------------|
| 2.6                        | 100 25                                                     | 1 2.4                                      |
| 1.3                        | 100 60                                                     |                                            |

From this result it follows that in chemical analysis, when exciting secondary lines with continuous radiation, we have to apply the same voltage at which the intensity ratio of the standard and the line in question was determined. Points of theoretical interest in connexion with the above results will be discussed in a detailed paper, one of these points being that the fluorescent yield of the total radiation emitted by the excited atom is dependent upon the exciting radiation.

### Determinism

IN his address on the decline of determinism,<sup>1</sup> Sir Arthur Eddington enunciates a very curious equation: "If the atom has indeterminacy, surely the human mind will have equal indeterminacy for we can scarcely accept a theory which makes out the mind to be more mechanistic than the atom." This statement will not bear too close an examination even from a non-quantitative point of view. Thus an attempt by myself to solve even a simple wave equation might lead to any of a large number of

results, a similar attempt by Sir Arthur Eddington would lead to the correct solution with a high degree of probability. I do not think that this proves that his mind is more mechanistic than my own, whatever that may mean. Actually it is generally regarded as a compliment to describe a person as reliable, that is, to suggest that his conduct is predictable.

Fortunately, however, quantitative data exist which seem to show that, as regards moral behaviour, some minds are decidedly more determined than are some atoms as regards radiative behaviour. Consider a given man  $M_1$ , and the probability  $p$  that between times  $T_1$  and  $T_2$  he will commit an action such as to lead to his imprisonment for a breach of the law. If we have no further information regarding  $M_1$ ,  $p$  is in most communities a small number, less than 0.01. If, however,  $M_1$  has a monozygotic twin  $M_2$ , brought up in the same environment up to the age of 14, and  $M_2$  is known to have been imprisoned for crime between the ages of 16 and 40, we can infer with a fairly high degree of probability that  $M_1$ , who has an identical nature and a similar nurture, has been or will be imprisoned between the same ages. Judging from Lange's<sup>2</sup> results,  $p$  is about 0.875 in south Germany when we have the above amount of information. If we increase the amount of information, for example, by excluding cases where  $M_2$  has suffered from head injury, the value of  $p$  is raised still further. Now, if it could be shown that with sufficient information  $p$  became unity in a case of this kind, we should, I take it, have proved the determinacy of some kinds, at least, of moral choice. Actually the most that scientific method can do is to prove  $p > 1 - \epsilon$ . If Sir Arthur Eddington is correct, then no matter how complete our information,  $\epsilon$  tends to a finite limit which is not very small. Clearly no amount of observation could prove it to be zero. But if it could be shown to be less than 0.01, we could neglect it to a first approximation in ethical theory, and if it proved to be less than  $10^{-6}$  we might hazard the guess that the behaviour of human beings showed no more indeterminacy than that of other systems composed of about  $2 \times 10^{27}$  atoms.

I think that it is a legitimate extrapolation from the existing data that if we used all the available data in the above case,  $\epsilon$  would be less than 0.05. It seems unfortunate that any attempt should be made to prejudge, on philosophical or emotional grounds, the magnitude of a quantity susceptible of scientific measurement. But from the heuristic point of view the deterministic theory has the advantage that it could be disproved, and would be if  $\epsilon$  tended to a finite limit as the amount of available information increased indefinitely. On the other hand, indeterminism cannot be disproved unless its supporters state the value of  $\epsilon$ , which they have so far carefully avoided. When the truth about human behaviour is discovered, it will probably appear that philosophers of all schools had failed to predict it as completely as they failed to predict Heisenberg's uncertainty principle. Human behaviour is a subject for scientific investigation rather than *a priori* pronouncements.

J. B. S. HALDANE

Royal Institution,  
Albemarle Street, London, W

<sup>1</sup> NATURE, 129, 240, Feb. 13, 1932.  
<sup>2</sup> "Crime as Destiny", 1931.

Is it really necessary to appeal to anything so *recherché* as Heisenberg's Principle of Indeterminacy in order to justify anything so familiar as personal freedom of choice? This question arises on reading Sir Arthur Eddington's interesting address in NATURE of Feb. 13. Consider any one of the laws of physics

commonly verified in the laboratory, say  $T = 2\pi\sqrt{l/g}$  for a simple pendulum. If, while one student is observing the pendulum, another student were to knock it about, the observations might misfit the formula. And so in general the accepted laws of physics are verified only if no person interferes with the apparatus. We cannot interfere with the moon, because it is so massive and so far away and that is part of the reason why the motion of the moon is almost deterministic, the 'almost' referring to the extremely small Heisenbergian indeterminacy. But there is no great mass or great distance to prevent John Doe interfering with his own brain in the act of making his decision to buy a house from Richard Roe.

### Catalysis in an Inert Solvent

It is becoming increasingly clear that carbon tetrachloride is an ideal solvent in the sense that it allows reactions of varying kinetic type to proceed in it at the same rate as they do in the gaseous phase.<sup>1</sup> This lends great interest to the results of Lowry and Traill<sup>2</sup> on the kinetics of the mutarotation of beryllium benzoylcamphor in this solvent. The reaction in pure carbon tetrachloride is very slow, but when catalysed by pyridine or ethyl alcohol, unimolecular constants are obtained which are proportional to the concentration of the catalyst.

The change is thus essentially bimolecular, and its rate must depend on the number of encounters between molecules of catalyst and of beryllium benzoylcamphor. Assuming the reactant molecule to be activated by the kinetic energy of the colliding molecules, it becomes possible to calculate the energy of activation according to the method of Lewis<sup>3</sup>

$$\frac{\text{Number of molecules reacting}}{\text{Total number of collisions}} = e^{E/RT}$$

By applying the gas formula to calculate the number of collisions,<sup>4</sup> taking the sum of the molecular radii as  $7 \times 10^{-8}$  cm, and  $T = 298^\circ$ , we find the values of  $E$  given below. These agree within the limit of measurable uncertainty with the experimental values found by plotting  $\ln k$  against  $1/T$ .

| Catalyst | $E$ (calculated) | $E$ (observed) |
|----------|------------------|----------------|
| Pyridine | 18,840           | 18,850         |
| Alcohol  | 18,410           | 18,690         |

Unless the agreement is accidental—and on the whole this seems most unlikely—the following points emerge. (1) The gas collision formula can be used to determine the number of collisions between two species of solute molecules present at low concentrations in an inert solvent. (2) Another example has been revealed of a reaction proceeding in solution at the same rate as theory would predict it to have in the gaseous phase. Deactivations by solvent molecules thus appear to be absent. (3) Lowry and Traill have succeeded, by the suitable choice of reactant, solvent, and catalysts, in examining a reaction which has all the characteristics of the simplest conceivable case of catalysis in solution.

## Ancient Windmills

ACCOMPANYING this note are two windmill illustrations (Figs. 1 and 2), one from Ramelli's "Le diverse et artificiose Machine", 1588 (Brit. Mus., 48, f. 15), and the other from the great Chinese Encyclopædia or "Ch'in Ting Ku Chin T'u Shu Chi Ch'eng", vol. 32,

FIG. 1.—Windmill in Ramelli's "Le diverse et artificiose Machine" (1588)

sec. 245 (Brit. Mus., Oriental students' room). For the benefit of readers of NATURE who may not be familiar with the Chinese Encyclopædia, I may say that the only complete copy of the first edition out-

FIG. 2.—Windmill in the Chinese Encyclopædia

side China is in the British Museum, consisting of 750 bulky volumes fully illustrated, and that the work was completed about two hundred years ago.

The illustrations will be of interest to students of technological history, as they appear to indicate that the Chinese encyclopædist had access to European sources and made use of them when compiling this work. I may say that I have found European counterparts of other illustrations in the Encyclopædia, a

number of horizontal windmill illustrations apparently having been copied with very slight modification from the "Machinae Novae Fausti Verantii" (Brit. Mus., 535, i. 16), published at Venice about 1692, and illustrations of sawmills, etc., from various European works of the sixteenth and seventeenth centuries. The most probable explanation seems to be that copies of these works were taken to China by Jesuit missionaries—Athanasius Kircher, for example.

## Heat of Dissociation of Oxygen

THE heat of dissociation of oxygen has given rise to some lively controversies in recent years. Mecke<sup>1</sup> concluded from the photochemical work of Norrish on NO<sub>2</sub> that  $D_{O_2} = 128$  kcal., a view which was supported by V. Henri<sup>2</sup> from the interpretation of the predissociation spectra of NO<sub>2</sub> and SO<sub>2</sub>. Birge and Sponer,<sup>3</sup> on the other hand, conclude, from the analysis of the Runge-Schumann bands, that the heat of dissociation in the excited state amounts to 162 kcal. Herzberg<sup>4</sup> was of opinion that the molecule in the excited state was made up of a (<sup>3</sup>P) oxygen atom and a (<sup>1</sup>D<sub>2</sub>) atom, hence subtracting from Birge's figures the heat of excitation to the <sup>1</sup>D<sub>2</sub> state, namely, 45 kcal., he gets the heat of dissociation of O<sub>2</sub> into two <sup>3</sup>P atoms as 117 kcal. This view seems to have been accepted by Franck, though Copeland<sup>5</sup> supports Mecke's value of 128 kcal. from his study of the heat of formation of the molecule from the atomised state in the discharge tube.

I have found that SO<sub>3</sub> vapour, in contrast with SO<sub>2</sub> vapour, which gives a band absorption, shows a continuous absorption with a long wave-length limit at  $\lambda 3300$ , corresponding to 86.7 kcal. From this data, assuming the reaction due to light to be given by  $SO_3 + 86.7 = SO_2 + O$  (atomic), I have calculated the heat of dissociation of oxygen with the aid of thermochemical data<sup>6</sup> for the heats of formation of SO<sub>2</sub> and SO<sub>3</sub>. The thermochemical relations are

$$(SO_2) + 69.3 = [S] + (O_2) \\ \text{and } (SO_3) + 91.9 = [S] + \frac{3}{2}(O_2).$$

This gives with the above relation the value of  $D_{O_2}$  as 128 kcal. The value is thus in agreement with the results of Mecke, Henri, and Copeland and does not agree with that given by Herzberg.

## A Symbol of the Space-Time Continuum

If a strip of stamp edging is taken, given a half twist, and the ends joined, we have formed one of the well-known paradromic rings, having only one surface and one edge.

The figure occupies three dimensions in space, but like time has the feature of endlessness, or like Einstein's finite space returns on itself. I suggest, therefore, that it may well stand for a symbol of the space-time continuum.

## Research Items

**Yuma Ethnography.**—A report on the results of two visits of ethnographical investigation among the Yuma Indians in 1928 and 1929 by Prof. C. Daryll Forde is published as vol. 28, No. 4, of the University of California's *Publications in American Archaeology and Ethnology*. The Yuma now occupy a reservation on the west bank of the Colorado River at the confluence of the Gila, which includes the greater part of the land which they occupied at the time of Spanish exploration. They have, therefore, suffered little disturbance; but owing to their assimilation of American culture, the material culture—basket-making, weaving and pottery-making—has disappeared, and so to a great extent has their social organisation. Their sense of tribal solidarity, however, is strong. Formerly they lived in scattered settlements near their patches of arable land and mesquite bushes. The men went naked, while the women wore a two-piece bark skirt. They resemble the other Indians of Colorado in their great stature. The people were agriculturists, depending upon the natural irrigation of the river overflow. They cultivated corn, beans, pumpkins, melons, and grasses. As a result of an intensive study of social organisation and ritual, it is concluded that the culture of the Yuma and other tribes of the Lower Colorado is remarkable in its divergence from that of the Pueblos and the Californians. Nor are they transitional groups. Although there are signs of fusion of south-western and Californian cultural traits, there are other elements which are strikingly individual. Thus, though they divide themselves into exogamous groups, these groups are patrilineal. Among the markedly individual traits is the subordination of wealth, hereditary right and ability, to the acquisition of supernatural power.

**The Buffalo-Fly Danger in Australia.**—The buffalo-fly (*Lyperosia exigua*) is not a native of Australia, but is supposed to have been introduced from the Indo-Malayan region with buffaloes imported by way of Melville Island, so early as 1825 (R. J. Tillyard, *J. Coun. Sci. Indust. Res.*, Australia, 4, 234; 1931). With the development of the pastoral industry in northern Australia, the fly began to take its place as an economic factor; for although it does not carry disease and does not kill its host, it sucks its blood and produces serious loss of condition due to 'fly-worry'. The point when toleration is replaced by nervous strain is represented by a concentration of about a thousand flies to each beast. The creatures attacked in Australia belong to a wider range than the hosts in the Netherland Indies, and include buffaloes, cattle of all kinds, horses, mules, donkeys, and occasionally man himself; but the serious aspect of the problem is that the fly shows yearly a wider range of distribution, having moved with cattle herds until it has spread over all the settled portions of the Northern Territory north of the 20-inch rainfall line. By 1910 it had reached Kimberley, and has become the worst cattle pest there. Beyond this northern range it is unlikely to pass by natural extension, because of the barrier of a dry belt, but there is great danger that it may be transported to south-western Australia through the uncontrolled importation of cattle from Derby to Fremantle, where the fly did appear in 1928 but was eradicated. Efforts are to be made by the introduction of parasitic insects so to reduce the numbers of adult buffalo-flies that they fall below the level which causes economic loss.

**Distribution, Ecology, and Classification of Tunicata.**—Dr. Harold Thompson has continued his study of

the distribution, ecology, and classification of the Tunicata of the Scottish area (Fisheries Board for Scotland, *Sci. Invest.*, 1931, No. 1, "The Tunicata of the Scottish Area. Part 2, The Styelids and Botryllids of the order Ptychobranchia"). The importance of physical environment in determining the distribution of the various species is stressed, and a list of records, with a chart showing the distribution, is appended to the description of the morphological characters of each species. The typical arctic, boreo-arctic, boreal, and south boreal forms are listed, with notes of the limiting conditions of temperature and depth of each type. Dr. Thompson maintains temporarily the separation of the Botryllidæ and Styelidæ until further investigations have been carried out on the methods of budding of the two families. The genus *Kuken-thalia*, whilst having obvious affinities with the other genera of the family Styelidæ, appears to possess a brood pouch of similar origin to that of the genus *Botrylloides*, and when the nature of the affinities has been fully disclosed it is probable that the Botryllidæ will have to be subordinated as a subfamily of the family Polyzoidæ, which Hartmeyer includes with the styelids. A single species of *Botryllus*—*B. schlosseri* Pallas—is retained, the old *Botryllus aureus* being regarded as a species of *Botrylloides*, with which genus it agrees in the nature of the systems, presence of brood pouches, shape of testes, and position of vasa deferentia.

**Zoning of Amphipod Species.**—Mr. Richard Elmhirst, director of the Scottish Marine Station at Millport, in a paper entitled "Studies in the Scottish Marine Fauna.—The Crustacea of the Sandy and Muddy Areas of the Tidal Zone" (*Proc. Roy. Soc. Edinburgh*, Session 1930-31, volume 51, part 2 (No. 21)), shows that a rich intertidal amphipodan fauna in certain areas of the Clyde, notably Cumbrae, exhibits zoning by species. *Bathyporeia guilliamsoniana* is the dominant low water form in the clean sand, beginning about low tide level and extending seawards to about four fathoms, with a definite maximum about low water. In Loch Gilp it suddenly disappears at about one fathom. *Corophium volutator* in the muddy brackish area of the high water region is very abundant, taking the place of *Corophium crassicornis*, which is the typical low water mark species. *Haustorius arenarius* is usually confined to the upper half of the intertidal area, preferring rather loose sands which often occur high up on the beach as a result of wind and wave action. The distribution of this species coincides with that of the annelid *Nerine foliosa*.

**Chromosome Linkage in Garden Peas.**—When a Tibetan variety of the cultivated pea (probably brought back by the Mt. Everest Expedition) is crossed with the English variety, Duke of Albany, there is full fertility except when a particular 'line' of the Tibetan pea is used. This line was shown to produce hybrids with a ring of four chromosomes and semi-sterility, half the gametes failing to mature. A further genetical and cytological study of these forms has been made by Caroline Pellew and Mrs. E. Sansome (*J. Genetics*, vol. 25, No. 1). Two other cases of ring formation, accompanied by linkage of factors which are normally independently inherited have been discovered in Swedish varieties of peas by Hammarlund and Håkansson. The chromosome carrying the factors for round and wrinkled cotyledon are in the chromosome ring in the Tibetan variety, the plants heterozygous for these factors being usually semi-sterile, but there are about one in eight

exceptions in each class. The fertile sister plants have seven bivalents. A cytological study of chiasma formation in the meiotic chromosomes shows that the results are in accordance with Belling's hypothesis of segmental interchange. The ring of four on the heterotypic spindle separates so that adjacent chromosomes go to the same pole, or in other words, double non-disjunction takes place, in about half the cases observed. It is suggested that this gives rise to the non-viable gametes, as such gametes will show genic unbalance, having two members of one pair of chromosomes and lacking both members of another pair.

**Timber Pit Props**—Apart from other dangers, the safety of the men working in coal mines is to a considerable extent dependent upon the strength of the pit props supporting the galleries. That this matter is one of primary importance becomes evident when it is remembered that timber is a very variable material. Work which has been carried out in this matter has been recently published in a brochure entitled "Tests on Timber Pit Props", by S. M. Dixon and M. A. Hogan (Safety in Mines Research Board, Paper No. 72, London: H. M. Stationery Office, 2s. net). In these tests the writers say "In one most variable batch of props the strength of the weakest prop was less than half the average strength and only about a quarter the strength of the strongest prop, though all the props were nominally similar." It is pointed out, a factor not always realised, that round untapered props are very rigid and comparable to rigid steel props. They therefore do not show an appreciable amount of shortening or 'give' before failure, and consequently are dangerous. To ensure the maximum 'give', which would render the approaching failure evident to the trained eye, it is suggested that the diameter of the small end of the taper should be half the diameter of the prop. These tests have covered a wide range and data have been obtained as to the average strengths of round props of home-grown and imported timber of various species, the average strengths of quartered and tapered props, the extent and nature of the shortening under load of untapered props and props with tapers of various forms, the effects of the rate of loading, repeated loading, and sustained loading, the effects of the moisture content of the timber, and the variations with time in the moisture content of props stacked in the open and under cover.

**Jurassic History of North America**—One of the most detailed palaeogeographical studies yet made, accompanied by fourteen maps of North America from the beginning of the Jurassic to the early Cretaceous, has been published by C. H. Crickmay (*Proc. Amer. Phil. Soc.*, Philadelphia, pp. 15-102, 1931). Each map represents the geography of a closely defined date, and the series is adequate to illustrate the culminations of all the notable geological events of the period. The results bring out the fact that there were four main marine transgressions: Liassic, Bajocian, Callovian, and Argovian. These seem also to have been world-wide transgressions, for they are represented in Europe and India. In North America the general surface was low and flat, and a comparatively slight down-warping would then cause wide marine expansion. Volcanic activity broke out vigorously in the Sonmian, in the later Middle Jurassic, and in the late Callovian, in each case in the extreme west from Alaska to California. Tectonic mountains (Agassiz orogeny) were built after the cessation of volcanic activity. The period ends with the more important Nevadan mountain building. North America was then mainly land with two areas of dominant continental sedimentation.

**Hawaiian Earthquakes, 1929-30**—A review of the remarkable series of earthquakes in these two years is given in the *Volcano Letter* issued by the Hawaiian Volcano Observatory for Nov. 5, 1931 (see also *NATURE*, 124, 851, Nov. 30, 1929). The total number of shocks recorded was 1516 in 1929 and 1070 in 1930. The large number in the former year was mainly due to the continued activity of a centre near the volcano Hualalai in the north-west of Hawaii, the numbers registered during the three weeks ending on Oct. 16 and Nov. 13 being 594 and 215 respectively. After the latter date their frequency declined, though, until the middle of March 1930, many tremors originated in the Hualalai centre. During the remainder of 1930 the seismicity of the island became normal, with a frequency of nearly a hundred shocks and tremors per month. It is suggested that the activity of the Hualalai centre was due to "lava flowing in under the volcano with an upward pressure, splitting open deep rifts, and preparing for eventual outflow somewhere to the north of the Mauna Loa centre."

**High Speed Ions**—The first December number of the *Physical Review* contains an article by D. H. Sloan and E. O. Lawrence, of the University of California, describing a method for producing very fast heavy ions (see also *NATURE*, July 11, 1931, p. 83). This does not call for unduly high voltages or elaborate apparatus, the desired acceleration of the ions being obtained by repeated application of a relatively small impulse. The ions, which are conveniently drawn from a low-voltage arc, travel through a series of metal tubes in synchronism with an oscillatory electric field applied alternately to the tubes in such a way as always to accelerate the ions passing from one tube to another. Using thirty such steps and a high-frequency potential difference of 42,000 volts at a wave-length of 30 metres, a current of  $10^{-7}$  amp of 1,260,000 volt singly charged mercury ions has been produced. The success of the method depends on the focusing and synchronisation of the beam of ions in the accelerating system, but it is apparently not difficult to effect this. The authors of the paper express the opinion that the production of 10,000,000 volt ions is an entirely practicable matter. The method is less readily applicable to light ions or electrons, on account of the great length of the apparatus needed for these.

**Electrical Protective Devices**—In the early days of electricity supply, the effects of dangerous currents were guarded against by using fuses in series with the circuit to be protected. This system proved quite satisfactory so long as the voltage was low and the power transmitted was small, but with high voltages the circuits need to be broken under oil. These oil circuit breakers are practically always of the automatic type. They are equipped with 'trip' coils or relays which, on the occurrence of abnormal conditions in the main circuit, release the energy stored in strong springs, and so the contacts separate in a small fraction of a second. In a paper read by C. L. Lipman to the Institution of Electrical Engineers on Jan. 8, improvements in the design of these relays are discussed. The advent of the national grid in Great Britain marks a new era in the history of British engineering, and particularly in the development of protective gear. The relays discussed are divided into classes. The first class includes those which prevent overload, the second prevents current leaking to earth, and the third prevents the current from running in the wrong direction. In the last case the relay prevents the generator acting as a motor and absorbing power from, instead of giving power to, a network. Mr. Lipman described a new relay which is very simple and trustworthy, and is

suitable for modern high power and high voltage circuits. Several hundreds of these devices have been in operation at places all over the world for five years and have given satisfactory service.

**Adsorption**—As is well known, Langmuir has advanced the theory that adsorption of gases on surfaces normally proceeds with the formation of a unimolecular film, and there is experimental evidence for the validity of this assumption. The most direct type of experiment involves the use of a crystal face as a plane adsorbing surface, and Bawn (*J Amer Chem Soc*, Jan) has described some measurements of the adsorption of some gases and of acetone vapour on cleavage plates of mica, which show that Langmuir's adsorption equation is closely followed in the cases of carbon monoxide and oxygen, a saturation value being reached which corresponds with one-third of the surface covered in the case of acetone. In no case was the film thicker than unimolecular, no evidence for capillary condensation being found for pressures up to one-thousandth of the saturation pressure. In the case of argon, no simple equation expresses the results. The pressures used in all the experiments were small and the temperatures low. The magnitude of the adsorption was found to be dependent upon the conditions of outgassing of the surface, which is explained on the basis of the concept of the activation energy for adsorption processes.

**Reaction Velocity**—Harned and Samaras (*J Amer Chem Soc*, Jan) have determined the velocity

of hydrolysis of ethyl orthoformate to ethyl formate in presence of a constant acidity maintained by an acetic acid-sodium acetate buffer in various solvents. The results show that, with the exception of the glycine solutions, all the other series of measurements in aqueous solutions of methyl, ethyl, *n*-propyl, isopropyl, and *n*-butyl alcohols, acetone, glycerin, and glycine show the following dependence of the velocity constant on the dielectric constant  $\ln k_0 - \ln k = 0.07(D_1 - D)$ , where  $k_0, k$  are the velocity constants in water and the mixed solvent, and  $D_1, D$  the dielectric constants of the latter, respectively. In a theoretical paper, the same authors attempt to show that the kinetic factor for medium effects can be expressed in the form  $e^{-W/RT}$  and to interpret  $W$  on the basis of electrostatics. They point out that the general problem is difficult, and confine their discussion to some important special cases. They start with a consideration of the energy change involved in the transfer of an ion from one medium to another of different dielectric constant, and with certain simplifications obtain an expression for the ratio of the activity coefficients in terms of the difference of dielectric constants. By introducing Huckel's equation for the activity coefficient of an electrolyte, they show in a number of cases that experimental results can be interpreted in terms of their theory, and conclude that the dielectric constant variation from solvent to solvent is the factor of greatest importance in causing changes in the velocity constant.

### Astronomical Topics

**Astronomical Notes for March**—The spring equinox occurs at 7<sup>h</sup> 50<sup>m</sup> P.M. on March 20. Full moon occurs on March 22, only 1½ days after the equinox, thus explaining the early Easter.

Mercury is well placed as an evening star during this month. It should be looked for low in the west in the later part of twilight. Venus may be used as a guide to it. The following table gives the difference of R.A. and Declination of the two planets.

|         | Mercury West                  | Mercury South |
|---------|-------------------------------|---------------|
| March 7 | 2 <sup>h</sup> 0 <sup>m</sup> | 14 2°         |
| 12      | 1 48                          | 12 0          |
| 17      | 1 40                          | 9 8           |
| 22      | 1 38                          | 8 3           |
| 27      | 1 45                          | 7 8           |

The magnitude of Mercury is -1.3 on March 7, +0.3 on March 27. It is at its greatest elongation, 19° from the sun, on March 23. Venus is drawing away from the sun, and becoming brighter. It reaches elongation on April 19. The illuminated portion of the disc is 0.73 on March 1 and 0.61 on March 31. The magnitude changes from -3.6 to -3.8.

Jupiter and Neptune passed opposition in February, and are still well placed for observation. There is an eclipse of Jupiter IV on March 14. It disappears at 7<sup>h</sup> 41<sup>m</sup> P.M., reappearing 35 minutes after midnight. III is also occulted and eclipsed from 8<sup>h</sup> 7<sup>m</sup> P.M. on March 14 until 3<sup>h</sup> 5<sup>m</sup> A.M. on March 15. Satellite I is occulted by IV at 11<sup>h</sup> 59<sup>m</sup> P.M. on March 5, III by IV at 2<sup>h</sup> 33<sup>m</sup> A.M. on March 7. There is an interesting double occultation of IV by I at 7<sup>h</sup> 23<sup>m</sup> P.M. on March 14 and 4<sup>h</sup> 40<sup>m</sup> A.M. on March 15. See the British Astronomical Association Handbook for 1932 for a complete list of these phenomena.

There is an annular eclipse of the sun on March 7, and an almost total eclipse of the moon on March 22. Both are invisible in Europe. The track of annularity in the former includes southern Tasmania shortly before sunset.

Only two occultations by the moon are visible during March in London, 38 B Aurigae (mag 6.5) disappears at 9<sup>h</sup> 55<sup>m</sup> P.M. on March 14,  $\tau$  Scorpi (mag 2.8) reappears at 3<sup>h</sup> 41<sup>m</sup> A.M. on March 27, at angle 262° (near the west point of the disc).

A minimum of Algol at a convenient hour occurs on March 10 at 9<sup>h</sup> 43<sup>m</sup> P.M.

The zodiacal light may be looked for at the end of evening twilight on dates when the moon is absent at that hour. It follows, approximately, the direction of the ecliptic, which is roughly determined by drawing a line from Venus to a point between the Pleiades and Aldebaran.

Search for the periodic comet Grigg-Skjellerup (which is due at perihelion on May 18) may be begun in March, as it is likely to be faint in March, the ephemeris is not given here (see the British Astronomical Association Handbook, 1932).

**New Solar Observatory of the Smithsonian Institution**—A *Bulletin* from the Smithsonian Institution, dated Feb. 1, announces that the solar observatory on Mt. Brukkaros, in South-West Africa, has been abandoned after a trial of five years, its drawbacks were haze and high winds. Several other mountains in South Africa were tried, also the Cape Verde Islands. Trial is to be made of Mt. St. Catherine, in the Sma. Range, 8540 ft. high. It is stated that the region is practically waterless and barren, and that the winds are light and come more frequently from the Mediterranean than from the desert, so that there should not be much dust.

The famous monastery of St. Catherine, where many valuable manuscripts were found, is not on this peak, but on the Jebel-Musa, some twelve miles distant. So much trouble has been taken by Dr. C. G. Abbot and his assistants in finding a suitable site, that it is to be hoped that their patience may at last be rewarded.

## Block-Movements in the Boso Peninsula (Japan)

PROF N MIYABE has recently published two remarkable papers on the movements of crust-blocks (*Earthq Res Inst Bull*, vol 9, pp 256-272, 407-422, 1931). It is clear that if a crust-block is tilted as a whole, there must exist a simple geometrical relation between the amounts of tilting in two different directions. Conversely, if this relation is satisfied by the tilts along neighbouring pairs of lines, Prof Miyabe regards the lines as lying on the same block. The papers are concerned with the crust-blocks of the Boso peninsula on the east side of Sagami Bay. The first survey of the district was made in 1898, the line of levelling being near the coast. It was repeated in 1924, shortly after the great earthquake of Sept 1, 1923, and again in 1931, and the two papers refer to the displacements that occurred during the intervals between the surveys.

In the accompanying map (Fig 1), the dotted lines represent the probable boundaries of the crust-blocks and the arrows denote the magnitudes and directions of tilting of the different blocks. The boundaries were drawn without any reference to geological maps, but several of them were found to coincide approximately with discontinuities in geological structure. These are shown as continuous lines. One of them is a well-marked tectonic line to the north of Kamogawa, and it will be noticed how different are the directions of tilting of the blocks to the north and south of this line.

The figures on the map denote the mean uplift of each block in inches between 1898 and 1924. It will be seen that there are three groups of blocks, in each of which the uplifts are approximately the same. In the south-west corner of the peninsula, they lie, as a rule, between 47 in and 51 in, with two exceptional amounts of 55 in and 61 in. To the north and east of this lies a group in which the uplift is confined between 23 in and 31 in, and, still farther, a third group in which the movements are between 8 in and 12 in, with two exceptions of 18 in and 22 in.

In the second paper, the changes of level that occurred between 1924 and 1931 are compared with those of the earlier interval. The curves representing

them show that, on the whole, the vertical movement was reversed. For example, a block elevated by 45 in in the first interval was depressed by nearly 4 in in the second. Though the constituent blocks

FIG 1

show a certain independence of movement, it would seem that the Boso peninsula underwent a general tilting towards the north-east in the first interval, and a return tilting towards the south-west in the second.

## Preservation of Italian Folklore

IN Italy under the Fascist government every encouragement has been given to movements which quicken national self-consciousness. Those who value tradition, whether for sentimental or for scientific reasons, will applaud the efforts of the Opera Nazionale Dopolavoro (The Workers' Leisure Hours Institute) to preserve the festivals, music, and dancing of the folk, which are endangered by the industrial development of the country. Now that Russia no longer pays heed to her saints, no country in Europe is so rich as Italy in festivals, and nowhere have they been celebrated with more ritual and greater enthusiasm. It would have been a calamity had they been allowed to lapse. This probably would have been the fate of many, had it not been for the 'Dopolavoro'. Their continued existence now seems assured.

An excellent account of the work of the Institute in this field, for which the president, S. Enrico Beretta, is responsible, has been published recently\*. The first section of the book, however, is devoted to a list of

the feste which are observed in the various towns and districts of Italy. They are arranged calendrically, and brief descriptions of the essential features are given in each case. Many are illustrated by excellent photographs.

The feste are usually observed on the feast-day of the patron saint of the district, or on some festival of the Church, but pagan affinities are generally fairly easy to detect. The central feature is normally a procession, in which the image of the saint is carried round the district in a cart or on a platform. Sometimes the cart is buried in flowers, sometimes the place of the saint and cart is taken by obelisks or gigantic towers, such as the *Ceri* of Gubbio or the *Gigli* of Nolo (Naples). It is a reasonable conclusion that in ancient days the gods were carried along these same ways to purify the lands and secure the fertility of the fields of their votaries. At Easter the *Scoppio del Carro* of Florence betrays clearly the purpose of the rite. A mechanical dove released from the High Altar ignites the squibs set around the *carro* as it stands before the cathedral. A successful explosion is hailed as a sure index of abundance in the coming

\* "Costumi, musica, danze e feste popolari italiane." Pp 218. Roma: Editore Opera Nazionale Dopolavoro, 1931. 10 lire.

harvest An almost identical ceremonial opens the fire festival in one of the Pardons of Brittany The Carnival even more surely points to its pagan origin in the celebrations described

The success of the Institute in stimulating and renewing popular interest in the *feste* has been much assisted by the revival of the competitions for dialect songs, of which several are quoted These are sung during the festivals Local dances and local music played on the people's instruments, such as the pipes and bagpipes of the Abruzzi, have been encouraged A great impetus was given to interest in the preservation of local costumes on the occasion of the marriage of the Prince of Piedmont, when 4000 individuals, representing all parts of Italy, dressed in the correct traditional costumes, paraded past the

Prince and his bride The programme, giving the list of costumes, with many illustrations, is repeated in the volume

While the object of the Institute is practical so far as it aims at the promotion and preservation of popular art and festivals, it does not neglect the interests of the student of custom Coloured photographs have been taken of all the peasant costumes and of a large number of the more important festivals Some have also been filmed A national committee is being set up in collaboration with the League of Nations for the scientific study of Italian folklore In the meantime the student of folklore will find much to interest him in the Institute's publication, while he will register a debt of gratitude for its respect for tradition

### Research in the Metropolitan-Vickers Laboratories

THE Metropolitan-Vickers Research Department at Trafford Park, Manchester, during last year has been making increasingly important researches to find the scientific data forming the basis of engineering development It has continued its researches on the effect of high temperatures on the materials used in turbine construction and on the slow rate 'creep' tensile tests on steels of various compositions and of various shapes The effects of thermal action which were found to make steel brittle have been investigated in the case of alloy steels The high-frequency furnace equipment of the Department has been found most useful in connexion with experiments on the properties of molybdenum steels As there is a great demand for accurate data about the thermal characteristics of metals, very sensitive apparatus was constructed with this end in view Prolonged investigations were made on the cooling effect of fins fixed on the outside of tubes carrying hot fluids Experiments were also made on the converse problem of the cooling effect produced when cold water flows in the pipes causing convection currents of cold air

Work has been continued on chromium plating, and the critical thicknesses of the nickel and chromium necessary to ensure protection of brass and steel have been determined Considerable difficulty had been experienced in the plating of high carbon spring steel, but satisfactory coatings can now be obtained on this type of material The application of cadmium plating as a corrosion resistant has been extended to various processes used in the shops

Much electrical and magnetic research work has been done in the Metropolitan-Vickers laboratories The heating of parts of steel structures due to the

eddy currents induced in them by conductors carrying large alternating currents in their neighbourhood has been investigated and methods have been devised for avoiding the production of this local heating in the structures Theoretical and experimental investigations have been carried out to settle questions which arise in the design of high-pressure voltmeters Continuous research is also being carried out with regard to the cooling radiators used on transformers The work on core losses has been carried out up to cores of 30,000 kva Other problems discussed in connexion with transformers show the great demands made on the physical knowledge and mathematical skill of the experimenters They discuss, for example, the distribution of the transient voltages in the coil windings, the effects of magnetic fields on the performance of precision current transformers, the design of high-frequency transformers and Petersen coils for the protection of overhead networks A 50,000-volt 10,000-frequency transformer has been constructed and satisfactorily operated

The research on the best heat treatment for magnet steels intended to be used in meters has been completed, and so also has the effect of current impulses on permanent magnets Three experimental acoustical investigations have been completed for the engineers of the Mersey tunnel, and experimental work has been carried out on methods of preventing the noise made by fans Preliminary tests were made on the 500-kw. valve used at the P O Radio Station at Rugby, and it was run up until its output was 520 kw The use of radio waves of lengths about one metre—'quasi-optical' waves—is being actively investigated and is said to be promising

### Specificity in Catalysis

IN the thirty-third Robert Boyle Lecture, Sir Frederick Gowland Hopkins deals with the "Problems of Specificity in Biochemical Catalysis" (Humphrey Milford Oxford, 1931) He points out that the isolation of biological products and the determination of their constitution are not the end-points of biochemical research, but rather steps on the path to the investigation of the dynamic events of metabolism in the living cell In these events catalysts play an important part Owing to their specificity it appears that there must be a large variety within the confines of a single cell the acceptance of this conclusion presents to many an intellectual difficulty, which Sir Frederick considers may be

profitably discussed anew in the light of the fresh facts which are now available

After a brief reference to the hydrolytic enzymes, of which a great variety is known, usually one for each stage in the hydrolysis of any complex molecule, recent work on oxidation is reviewed Many oxidations are carried out by dehydrogenases which activate the hydrogen in the oxidisable molecule so that it can be taken up by molecular oxygen or other hydrogen acceptor The xanthine oxidase can transfer hydrogen direct to molecular oxygen other dehydrogenases can transfer it direct to an acceptor such as methylene blue, but not to oxygen until the latter has also been activated. Keilm's cytochrome,

an iron-pyrrol compound, plays an important part here activated by indophenoloxidase, it acts as an intermediate carrier of hydrogen to oxygen from the various substrates activated by the dehydrogenases.

Warburg considers that his respiratory enzyme, again an iron-pyrrol derivative, controls the whole field of oxidations. It shows no spectrum, in contrast to cytochrome, but forms reversible combinations with carbon monoxide as well as oxygen, the former of which is decomposed by light. By examining the effectiveness of different wave-lengths in restoring respiration after it had been inhibited by carbon monoxide, Warburg was able to determine the absorption spectrum of the enzyme, since light must be absorbed by the carbon monoxide compound in proportion to its effectiveness in dissociating it.

Another path for the transport of hydrogen to oxygen is that associated with the reduction and

oxidation of glutathione. Quantitatively it is less prominent than the cytochrome path, but it is essential to the normality of the cell. The cytoplasm of the latter appears to be a lyophil colloidal system in which the micellæ or particles which form the internal phase must be diverse in respect of their surfaces, and probably no small proportion of these surfaces have catalytic properties. Considering the size of the cell and that as much as 75 per cent of cytoplasm is water, of which much is free, it may be assumed that diffusion, as known in macro systems, plays only a negligible part in the velocity of change here, and that contacts between substrate molecules and dispersed particles with catalytic surfaces must continually occur. In such a system a multiplicity of reactions does not appear impossible, whilst the immense numbers of cells in a tissue permit of macroscopic quantities being metabolised.

### Sir Ambrose Fleming and the Physical Society of London

THE meeting of the Physical Society held on Feb 19 marked an event which is probably unique in the history of learned societies. If we open the Society's first minute book (which has fortunately been preserved) we find that the young Society held its first business meeting on Feb 14, 1874, when, 29 members being present, a list of officers was drawn up. Dr J H Gladstone, F R S, father-in-law of the present Prime Minister, was elected to the presidential chair, Profs Grylls Adams and Carey Foster were appointed as vice-presidents, Dr E Atkinson and Prof A W Remond were joint secretaries, and—the holder of an office which has fallen into abeyance—Prof Frederick Guthrie was appointed as the Society's demonstrator.

The next record on the minutes must be transcribed *literatim*. It reads—"A meeting of the Society was held in the Physical Laboratory, South Kensington Museum, at 3 P M on Saturday, March 21st [1874], Dr Gladstone in the chair. There were about 35 members present. The chairman gave a brief description of the objects and organisation of the Society, and noticed the very favourable circumstances under which the Society originated as compared with those attending the origin of its parent, the Royal Society. He announced that 99 gentlemen had already expressed their desire to join the Society as original members."

"J A Fleming, B Sc, read a paper on the new Contact Theory of the Galvanic Cell. Professor F Guthrie exhibited experiments illustrating the distribution of a galvanic current on entering and leaving a conducting medium."

"Prof G C Foster, Dr Wright, and Dr Gladstone took part in the discussion of the communications."

Can any other society produce such a record? It may be that a greater span of years separated Laveing's first and last papers read before the Cambridge Literary and Philosophical Society, but we know of no other instance in which the reader of the first paper at the first scientific meeting of a society has survived to communicate a paper to the society nearly sixty years later.

Inspection of the list of members published in 1930 shows that, of the founder fellows, four—Armstrong, Fleming, Schuster, and Unwin—are still with us. Lodge joined the Society in February 1875, and of those who entered the ranks in the 'seventies, fourteen still remained at the time of publication of the list consulted. President and Council have long since

disappeared—Carey Foster was probably the last survivor of the original officers—but it would be interesting to know if any of the early members were present when "J A Fleming, B Sc" presented his paper.

It is a far cry from the contact theories of 1875 to the wave mechanics of 1932, and Sir Ambrose Fleming has not only made history in this interval, but also still holds a place on the stage of contemporary events. He has read some thirty-five papers before the Society, and his latest paper, on "Electrons and Light Quanta", admirably illustrates the conservation of his powers as teacher and experimenter.

In his introductory section, Sir Ambrose states, clearly and succinctly, the fundamental facts concerning the antinomies, which, even though as yet unsolved, have almost ceased to perplex us. He calculates the value of the mean energy density of bright sunlight at earth distance, and, using four methods, he obtains from the mean of 10 equidistant ordinates of the Planck curve, 48, from the solar constant, 45, from the Stefan constant, 54, from the integration of the Planck equation, 55—all expressed in micro-ergs per cubic centimetre. As the illumination of bright sunlight is about 13,000 candle-feet at normal incidence on a white surface, it is possible to estimate the radiation density of other light beams and the average number of photons per cubic centimetre.

Experimentally, Sir Ambrose proceeded to investigate the question, which he states thus: "If then a beam of light can in any way be regarded as a stream of photons or light quanta each having energy and mass, and if the wave energy is electromagnetic in nature, the question arises whether a stream of electrons moving along a beam of light would have their velocity increased or diminished according as they moved with or against the direction of propagation of the light."

As a preliminary experiment with an arc lamp showed no result, Sir Ambrose employed a powerful beam of X-rays. The source of electrons was a special form of Fleming thermionic valve with a dull-emitter filament and two grid anodes of rectangular section fixed on either side. Hence if "a beam of radiation was passed transversely across the valve the electrons on one side of the filament moved against the radiation and on the other side with it". A simple circuit was arranged which would show by means of a differential galvanometer whether the

incidence of the X-ray beam produced any steady variation from equality in the two electron streams to the two anodes of the valve. No change was detected, although the galvanometer was competent to show a change of 0.05 per cent of the anode electron-currents to the grids. ALLAN FERGUSON

### Archæology of Eastern Colorado

THE archæological survey of eastern Colorado carried out in the summer of 1930 by the University of Denver and the Colorado Museum of Natural History, under the direction of Dr. E. B. Renaud, with the assistance of a subsidy from the Smithsonian Institution, is the first systematic archæological work undertaken in that area, and links up the exploration of south-west Colorado on one side, and of Nebraska and States east on the other. Ten thousand miles were covered in ten weeks. A large number of surface finds were collected, but no excavation was possible in the time. The report of Dr. Renaud and his assistants (published by the University of Denver, Anthropological Department) states that few important sites were left unvisited, and the collections and notes, while not exhaustive, are fairly representative of the Indian culture of Colorado.

The area of closest settlement is in the north-west, in Larimer County, with thirty-eight sites. The contiguous counties, extending from the Rocky Mountains to the States of Nebraska and Kansas without a break, form a vast central group separated by a trough from the smaller and isolated north-west group.

The camp site is the most common (247). Here flaked artefacts and chips are fairly well grouped. Old fireplaces and tipi-rings—stone circles, on which the skins rested, marking the base of the tent—are the most certain criterion of a camp site. An unexpected number of the grinding-stones known as *mano*, or hand-stone, were found. The *mano* is smaller in the pueblo area. Pottery, previously accounted unknown or rare in the western plains, was recorded on fifty-five sites. Fifty-two workshop sites and fifteen rock-shelters were visited. Petroglyphs, rarely painted and most commonly pecked, were found on fourteen sites. Dr. Renaud has made a careful study of the stone implements, comparing them exhaustively with those of the stone age of Europe and other parts of America. The greater number are non-palæolithic, next in importance being Mousterian-like points, scrapers, and flakes.

In 1931, according to a communication we have received from the Department of Anthropology in the University of Denver, the expedition covered the archæologically rich area known as the "Spanish Diggings" in the neighbourhood of Cheyenne and Larimer. About two hundred Indian sites were visited and recorded, and a large number of artefacts were collected. The pictographs were fewer in number than was expected. Pottery was found on a number of sites, and a number of camps showed tipi-rings. The expedition was particularly impressed by the resemblance of old quarries, from which red chert, yellow jasper, and quartzite have been obtained, to the prehistoric quarries of western Europe, except for the fact that the latter had yielded flint. The relative age of these quarries is being investigated by the examination of the growth of lichen. A rapid excursion was made to north-east Wyoming, archæologically a much less interesting area, but it is anticipated that western Wyoming, when its turn comes for exploration, will yield interesting remains, especially in the form of pictographs.

No 3252, Vol. 129]

### University and Educational Intelligence

**BIRMINGHAM**—In his report to the annual meeting of the Court of Governors held on Feb. 25, the vice-chancellor and principal, Sir Charles Grant Robertson, gives the figures for the number of students. The total for the past session was 1890, which approaches the maximum reached in the 'boom' period after the War. The new entries for the present session also show a marked increase. The postponement for a year (on account of national financial stringency) of the building of the new Hospital Centre and Medical School is a matter of grave concern, in view of the increasing congestion of the present buildings.

**CAMBRIDGE**—A report of the Syndicate on the Scott Polar Research Institute recommends that steps be taken to proceed with the erection of a polar research institute on the Lensfield site. The generous gift of £4000 by the trustees of the Pilgrim Fund last year has now made up the capital of the building fund to £12,000, which is considered sufficient to provide for the cost, equipment, and maintenance of the institute which the Syndicate has in view. The financial board while raising no objection to the recommendations has expressed the hope that every effort will be made to increase the endowment of the institute.

**LONDON**—Dr. G. F. J. Temple, at present reader in mathematics at the Imperial College, Royal College of Science, has been appointed to the chair of mathematics at King's College, as from Aug. 1.

The William Julius Mickle fellowship for 1932 has been awarded to Dr. Philip Eggleton, for his research on the labile compounds of phosphorus in muscle.

THERE will be an election to Beit fellowships for scientific research in July next. Applications, upon a form supplied upon request, must be received by April 12 by the Rector, Imperial College of Science and Technology, South Kensington, S.W. 7.

THE annual examinations for a Faraday scholarship of eighty guineas per annum, tenable for two years in the Faraday House Electrical Engineering College and one year in a manufacturing works, and for a Maxwell scholarship of sixty guineas per annum tenable for two years in the College and one year in a works, will be held at Faraday House on April 5-7. Further particulars may be obtained from the Registrar, Faraday House Electrical Engineering College, 62-70 Southampton Row, W.C. 1.

THE Rockefeller Foundation's disbursements in 1930 amounted, exclusive of administration expenses, to nearly fifteen million dollars, of which universities and other educational institutions received more than six millions, research institutions and organisations more than two millions, whilst public health work absorbed nearly three, and fellowships and grants in aid more than one million. The field of the Foundation's activities embraces, in addition to its International Health Division in which expenditure since 1913 has amounted to 42 million dollars, work in the medical sciences, natural sciences, social sciences, and the humanities. In the International Health Division particular emphasis has in recent years been laid on field work, including the gathering of knowledge about widespread maladies such as hook-worm, malaria, pellagra, yellow fever, tuberculosis, and the common cold. All results of researches by members of the field staff of the Foundation or by persons working under its auspices are published (to the number of 57 in 1930).

in the medical journals International Health Division fellowships are given to graduates in medicine of high professional standing and assured of positions in the public health services of their own countries In 1930, 173 such fellowships were held by natives of 33 countries, including the United States and its dependencies (52), China (18), Canada (12), Italy (12), other European countries (47), Brazil (8), India (8) In addition, the Foundation supported 102 fellowships in medicine for the supplementary training of young graduate physicians, from 35 countries, in preparation for definite positions in research or teaching Among enterprises aided by the Foundation are an institute of experimental biology in Copenhagen, an institute of cell physiology in the Kaiser Wilhelm Institute of Biology, and the Kaiser Wilhelm Institute for Brain Research

### Calendar of Geographical Exploration

#### March 2, 1705 — Coast of Northern Australia

Maarten van Delft sailed from Timor and surveyed the coasts of Melville Island and of the Coburg Peninsula, thus supplementing Tasman's chart of the region One of the vessels penetrated some distance into Dundas Strait

#### March 4, 1519 — Cortes in Mexico

Hernando Cortes landed in Mexico The discovery of Mexico by Juan Grijalva led Velasquez to entrust to Cortes the exploration and conquest of the country Starting from the coastal regions near the modern Vera Cruz, Cortes marched to the city of Mexico, sending a party to explore the snow-clad Popocatepetl *en route* The city was captured in August 1521, and Cortes sent out exploratory parties in all directions, Alvarado making some conquests in Guatemala Cristobal de Olid, who had been ordered to reach Cuba via Honduras, reached the southern shores of the gulf, but mutinied against Cortes The latter left Mexico in 1524 and marched through Tabasco to the Gulf of Honduras There he again sent out exploring parties from the town now known as Puerto Cortes and later from Trujillo

#### March 4, 1791 — Islands of the Pacific

Capt Edwards, in the *Pandora*, sighted Easter Island on a voyage undertaken partly in search of the mutineers from Bligh's vessel These men had apparently appreciated life in the South Sea islands so much that they wished to remain Some of them successfully settled in Pitcairn Island Edwards discovered some small islands in the Low Archipelago, and later, in his search for the mutineers, covered much of the Pacific not usually touched in trading voyages, thus many previously unknown islands were charted In the neighbourhood of Torres Strait the *Pandora* was wrecked, some of the crew were drowned, but others escaped in the boats and after terrible hardships reached Timor

#### March 4, 1905 — Charcot Land

Dr Jean Charcot in the *Français* arrived in Puerto Ladrada, Argentina Charcot had planned a voyage to the Antarctic to rescue Dr O Nordenskjöld, but this had been effected by an Argentine vessel Charcot then, in the course of two summer cruises, surveyed parts of the west coast of Graham Land and reached Alexander I Land His vessel was delayed by ice and anxiety was felt about its possible fate, but in spite of severe damage it escaped In 1908-10, Charcot returned to the Antarctic and discovered the land which now bears his name

### Societies and Academies

#### LONDON

Royal Society, Feb 18 — D'Arcy W Thompson The geometry of the siliceous skeletons of the Radiolaria. The figures of equilibrium and minimal area which are assumed by soap-films in Plateau's experiments have proved helpful in explaining the configurations of various cells and simple tissues in plants and animals Among the most curious and anomalous of cell-forms are those of certain Radiolaria In some of these the skeleton resembles a minute spiked helmet with three curved lappets or straps below Even such an anomalous configuration as this may be precisely imitated or reproduced by an artificial system of liquid films — H W S. Massey and C B O Mohr The collision of slow electrons with atoms (1) The theory has been developed in which the zero approximation is not a plane wave but the wave representing the motion of the electron in the static field of the atom concerned Exchange does not become very important until voltages lower than those obtained on Born's theory using the plane wave as first approximation At lower voltages, strong interference effects occur between the incident and exchanged electron waves, giving peculiar angular distributions of the scattered electrons These effects are observed experimentally — H C Webster The artificial production of nuclear  $\gamma$ -radiation The production of nuclear  $\gamma$ -radiation by bombardment with  $\alpha$ -particles has been observed for the elements Li, Be, B, F, Na, Mg, Al Negative results were obtained with H, C, N, Ni, Cu, Sn The absolute efficiencies of production of the various radiations range from about 0.5 quanta per million  $\alpha$ -particles for magnesium to about 30 quanta for beryllium In addition, the way in which the efficiency of production varies with the residual range of the  $\alpha$ -particles was investigated The processes probably responsible for the radiations are discussed some appear to be due to the capture of an  $\alpha$ -particle by a nucleus without proton emission, others are probably due to a secondary process following proton emission, others may arise from inelastic collisions without capture

Geological Society, Dec 16 — J E Richey The Tertiary ring complex of Slieve Gullion (Ireland) This complex lies west of the Mourne Mountains and north-west of the Carlingford Peninsula Topographically, it consists of a ring of curving ridges and hills, 7 miles in diameter, which is bisected by a mountainous belt extending to the north-west The ring and the north-west belt mark the outcrops of a very simple ring-dyke complex and later Tertiary plutonics The ring complex forms a complete ring, except to the south-west, where it is broken through by the north-west belt The almost exact coincidence of the ring-fissure with the margin of the western portion of the Newry granite is perhaps its most remarkable feature The constituent rocks of the ring are given

#### PARIS

Academy of Sciences, Jan 11 — E Jouguet Remarks on a theorem of Hugoniot relating to the flow of fluids — Maurice Hamy A property of the equation obtained by equating to zero the distance of two planets,  $P, P_1$ , which do not meet at real points — Paul Qvale Remarks on Thiele's semi-invariants — Georges Bouligand Various problems of infinitesimal geometry — N Aronszajn The decomposition of uniform functions — W Orlicz Some theorems on orthogonal developments — René de Possel *Étudiées* functions and ensembles of the

maximum type—E. Kogbetliantz The convergence of Hermite's series—N Abramesco The determination of holomorph functions in given domains—Marcel Guillot Reade's iriscope and the aptitude of solid and liquid surfaces to be moistened by water This method of testing the cleanness of a surface is based on the condensation on the surface of a small quantity of water vapour and subsequent examination of the interference effects produced Glass cleaned with hot sulphuric acid containing chromic acid is found to be clean only in certain spots Only surfaces obtained by fracture, by fusion, or prolonged treatment with hydrofluoric acid were found to be perfectly clean when tested by this method—E Henriot and O Goche Cathodic sputtering in a magnetic field Cathodic sputtering in a magnetic field produces a deposit on a screen, the position of which varies on reversing the field This deposit is due to carbon, and is independent of the nature of the metal employed as the cathode The origin of the carbon is discussed—Georges Fournier and Marcel Guillot The increase of absorption of the  $\beta$ -rays in molecules possessing certain linkages between the atoms—André Chevallier and Pierre Dubouloz The application of fluorescence to photometric measurements in the ultra-violet J and J F Thovet have proposed the utilisation of photoelectric cells with thin walls (the latter being covered with a thin layer of a fluorescent substance) for detecting radiations of short wave-length This method has been studied in detail with special reference to the composition of the fluorescent layer An emulsion of dextrin and sodium salicylate has been found to give the best results—Marcel Godchot, Etienne Canals, and Mlle Germaine Cauquil The Raman spectrum of some cyclohexane hydrocarbons Comparison of the Raman spectra of cyclohexane, methylcyclohexane, the three isomeric dimethylcyclohexanes, and of hexane The spectra are generally similar, but there are differences to which attention is directed—Henri Lafuma The solution and hydration of quicklime in the presence of calcium sulphate—E Herzog and G Chaudron The methods of testing the corrosion of metals Comparison of the effects of uniform and localised corrosion Localised corrosion, in which no appreciable loss of weight of the specimen is noted, may have a marked effect on the mechanical tests—G Darzens and Georges Lévy The method of preparation of phenols by the direct dehydrogenation of the corresponding hydroaromatic ketones Application of the removal of hydrogen by heating with sulphur—Charles Dufraisse and Léon Enderlin The formula and constitution of a colourless hydrocarbon with a violet fluorescence,  $C_{42}H_{26}$ —M Battegay and J Meybeck The amino-sulphonamides By the interaction of *N*-chlorosulphonylacetyl chloride,  $C_6H_5(CO \cdot CH_2)N \cdot SO_2Cl$  upon dimethylamine, phenylaminodimethylsulphonamide ( $C_6H_5 \cdot NH \cdot SO_2 \cdot N(CH_3)_2$ ) is obtained The dimethylamine can be replaced by other amines, giving the corresponding amino-sulphonamides—Mme Ramart-Lucas and Mlle Biquard The prediction and verification of the colour differences between isomers—A Marin and P Fallot The geology of the Punta Pescadores region (Spanish Rif)—A Dauvillier The theory of the polar aurora—Robert Lemesle A structural peculiarity in the various species of *Kadsura* The presence of small crystals of calcium oxalate in certain tissues appears to be general in all species of *Kadsura*—Pierre Chouard The diversity of the generic characters of the flowers, bulbs, and seeds in the genus *Ornithogalum*—P Lebard The influence of altitude on the tuber formation of the potato The existence of an optimum altitude Comparisons of tuber formation

of the potato at altitudes of 214, 1500, 1650, and 2100 metres above sea-level The alpine climate favours tuber production, the highest yields being obtained at 1500 metres—A Policard, A Morel, and P P Ravault The histospectrographic study of the localisation of calcium and magnesium in the human aorta, and their variations during atheroma—Émile F. Terroine and Mlle Marguerite Champagne The influence of the acid-base ratio of diet on the magnitude of the nitrogen metabolism—Émile Guyenot and Mlle A Moskowska and K Ponse The direct action of the hypophysis on the nuptial pad of *Bombinator pachypus*—Mme Y Khouvine, G Champetier, and R Sutra The X-ray study of the cellulose of *Acetobacter xylinum*—René Legroux Transmissible bacterial lysis The principle producing lysis behaves towards antiseptics as a diastase That it is a living organism is shown to be improbable

#### MELBOURNE

Royal Society of Victoria, Dec 10—A B Edwards The dacite-granodiorite contact relations in the Warburton area A granodiorite of Upper Devonian age is found intruding a contemporaneous series of dacites in the Warburton area (Victoria), at Nyora (Mt Tool-be-wong), and south of Warburton township At Nyora the dacite is but slightly altered At Warburton three members of the dacite suite enter the metamorphic aureole of the granodiorite, and are converted into ortho-schists and ortho-gneisses, with accompanying mineral changes As the granodiorite is approached, hypersthene is replaced by biotite, which in turn gives place to green hornblende A patch of anthophyllite-garnet rock is developed from the hypersthene-dacite, apparently by repeated metamorphism Andalusite is developed in the metamorphosed argillaceous sediments of Silurian age which enter the contact aureole—Elizabeth A Ripper Palaeontological zoning of the Lower Ordovician near Inghston The Lower Ordovician slates and sandstones, three miles south-east of Inghston, are shown by their graptolite faunas to belong to the uppermost zone of the Castlemaine series and all the Darriwil series, with the exception of the uppermost zone (D 1) Passage beds between D 5 and D 4 with *Oncograptus upsilon* and *O. biangulatus* have been recognised The area is the western limb of a geosyncline, of which the axis is unknown, since there is a passage from C 1 in the west to D 2 in the east, where beds of this age outcrop in the Werribee Gorge.—Frederick Chapman Some palaeozoic fossils from Deep Creek and Evans' Creek, Saltwater River, Victoria A preliminary note on the Deep Creek fossils by the author, published in 1903, gave a Silurian (doubtfully Yeringian) age to the collection from that locality The conclusions now arrived at are a Silurian age for both collections, with a leaning towards the lower or Melbournian stage—Walter J Parr Victorian and South Australian shallow-water Foraminifera (2) This part deals with the remainder of the material studied in Part 1, together with some additional species discovered since The new species are *Gaudryina hastata*, *Vaginulina vertebralis*, *Bohvinella elegans*, *Reussia armata*, *Discorbis australis* *D. collinsi*, and *Anomalina nononoides*—S Illichersky Does the flowering of plants of the Victorian flora repeat the order of their evolution?—Jean Heyward The relation between flowering and degree of evolution—Donald McCance Weathering of the older basalt of Royal Park, Melbourne A series of chemical analyses of different stages of decomposition of the rock, from the fresh basalt to the residual clay, are given By means of a table based on these analyses the calculated losses of material, due to weathering, in the various stages, are compared A

petrological description of the basalt is given, whilst the evidence points to the decomposition having been caused by infiltration of solutions from without — F A Singleton Studies in Australian Tertiary Mollusca (1) This paper deals with the status of fossils hitherto recorded as *Nucula obliqua* and *Lumopsis insolita*. Included in the paper are descriptions of the following new species and sub-species from the Australian Tertiaries *Nucula kalmanæ*, *Glycymeris granti*, *Lumopsis chapmani*, *L. chapmani valida*, *Cucullæa corcoensis prelonga* — David E Thomas The Kerrie series and associated rocks The Kerrie series of conglomerates and associated sandstones, to which various ages of basal Upper Ordovician and basal Silurian have been given, rests unconformably on the upturned edges of the Upper Ordovician The Lower and Upper Ordovician of the area are conformable, and no stratigraphical break has been proved between the Upper Ordovician and the Silurian On the similarity to rocks elsewhere in the State an Upper Devonian age is assigned to the conglomerate

## Science and Society

THE leading philosopher of the United States, Prof John Dewey, has in his latest book ("Philosophy and Civilization" \*) joined heartily in the campaign often urged in these columns for a larger scope for science and the scientific spirit, especially among educators and those responsible for social and political action. We are not offering an ordinary review of Prof Dewey's book, as the bulk of it consists of reprints of articles on detailed philosophic questions. But the concluding essay, under the title at the head of this article, is freshly published and raises a large number of tremendous questions in small space. They all merit a treatise apiece, with several supplementary chapters on points suggested but not brought out. One need scarcely say that on the main contention we are in full accord with Prof Dewey. He sums this up in his concluding paragraphs, that "the great scientific revolution is still to come", and that "it will ensue when men collectively and co-operatively organise their knowledge to achieve and make secure social values". "We are living in a period of depression. The intellectual function of trouble is to lead men to think. The depression is a small price to pay if it induces us to think about the cause of the disorder, confusion, and insecurity which are the outstanding traits of our social life. If we do not go back to their cause, namely, our half-way and accidental use of science, mankind will still pass through depressions, which are the graphic record of our unplanned social life. But it is incredible that men who have brought the technique of physical discovery, invention, and use to such a pitch of perfection will abdicate in face of the infinitely more important human problem."

These are true, brave, and wisely hopeful words. We agree wholly with Prof Dewey in his ultimate confidence, and sympathise with him in his chafing at the selfishness and obscurantism which prevent a more rapid advance. But one gains here and there in his article an inkling that the position in the United States must be in some respects more difficult than it is with us. For example, he refers in one place to "the obstacles against which social insurance with respect to accidents incurred in industrial employment had to contend", and says "that the idea of insurance against the risks of maternity, of sickness, old age, and unemployment is fought by all reactionary forces". Here, apparently, the Old World is actually more up to date

\* *Philosophy and Civilization* By Prof John Dewey Pp 334 (New York Minton, Balch and Co, 1931) 5 dollars

ST MARTIN'S STREET, LONDON, W C 2

No 3253, Vol 129]

than the New No one could use such language of the State insurance schemes now in operation in Great Britain We have made mistakes of detail in framing them, but they were accepted and welcomed generally by all parties, and it is a commonplace among us that had it not been for such scientific prevision the aftermath of the War would have been incalculably worse—something, in fact, that we shrink from contemplating Prof Dewey invokes Condorcet, in his prison at the Revolution, as the pioneer in applying the calculus of probabilities to insurance against social risks It is well to do so, for many of the most fruitful ideas which are now transforming society were first proclaimed at that time But we on this side of the water should not forget to add the name of Josiah Royce, one of America's most profound thinkers, who worked out on a larger and more practical scale the idea of insurance which had dawned on Condorcet

One gathers, indeed, not only from Prof Dewey's book but also from many other sources, a picture of American mentality of extraordinary interest and acute contrasts There is, on one hand, a much more widely diffused spirit of questioning and of eagerness for some new thing, and, on the other, a more obstinate individualism and a clinging to traditional views as a shibboleth We have nothing quite like that in Great Britain, and it must make any advance on the path of organising society on a scientific basis much more difficult If we may not interpret the legends of Genesis on scientific canons, how shall we fare in dealing with birth-control or the international settlement of the economic crisis?

This brings us to the point for which this article is written—very far, of course, from sermonising to America, the advanced and generous spirits of which have laid the whole world so deeply in their debt But the point is this The science which is to regenerate or reorganise society must be a completely human creation, universal both in its origins and in its outlook Prof Dewey refers at some length, and with a qualified approval, to the Five-Years Plan in Russia Both the reference and the qualified approval are natural enough, but he does not qualify for the most serious reason Drastic political methods, though we may disapprove, are less serious ultimately if they remain domestic The permanent menace and most solid ground for the criticism of the Russian experiment is that she has been proceeding in avowed hostility to the rest of the world Her science is a thing of a special brand, unlike that of the bourgeois world, and to be used to overthrow it *In hoc signo non vinces!*

A similar moral might be drawn, *mutatis mutandis*, from pre-War Germany One does not wish now to be discussing war-guilt, but it is essential to notice that the application of science to social reform, if it is to be permanent and avoid the convulsions and setbacks of the past, must be on an international basis

The working formula under which national and international applications of science to life are to be reconciled is now being worked out by mankind It involves all the most delicate and complicated of contemporary problems, some of which find their solution by waiting and patient trial and goodwill This, perhaps, may be the case with the currency question, but it is certainly not so with all Some demand vigorous initiative and, above all, the alignment of more than one nation in the interests of all the rest We know well that, when the great occasions come, we can count on a host of Americans, of whom Prof Dewey is a notable exponent, to stand for a sane internationalism, scientific by the very nature of the modern world, but also humane The latter condition, unhappily, does not follow as a matter of course Our thoughts are now all turning to the world conference on disarmament There is, no doubt, room for wide difference of opinion on the extent of the armed forces necessary for police and protective purposes by the several States, but there can be none as to the inhumanity and insane misuse of science in the continued elaboration of the submarine and poison gas, *et hoc gens omne* of modern warfare America, we are confident, will stand by us in withstanding the whole hideous business, or at least in relegating it to an international police force, according to Major David Davies' carefully thought-out suggestion

It will be said, no doubt, that it is a matter of education and that the governments of the world cannot go beyond the public opinion of their people This is true only with such qualifications that it might almost be denied All great populations, even the more educated, are capable either of mass suggestion or of intelligent guidance, if they are wisely led and the right method of approach is taken Here is such a moment and an irrefragable cause, in March 1932

For the ordinary education of the modern man in the ways of science and of peace, we should probably look, more than Prof Dewey seems inclined to do, to the older literary and historical curriculum transfused by science He speaks throughout of freedom and allowing the young to inquire and to think for themselves. Without disparaging this,

which is a common attribute of the young, mature opinion on this side would probably give the higher place to synthesis, to inducing in the minds of students the idea that harmony, both in our own minds and the world, is a possible ideal. Science was born from the agreement of minds, and we are now regaining a larger unity by the path of diverse specialities all subserving the common good, and an incomparable richness of knowledge drawn together by similar methods of thought. What we need to reform our higher education in Great Britain—we must leave America to speak for herself—is a strong strain of scientific thinking among those doing mainly literary studies, and for those on the ‘science side’, a recognition that science and technology have also their history, that they are the fruit of time and of collective and continuous effort, and that their results must go back to enrich the human soil from which they sprang. F S MARVIN

### Short Reviews

*The Archaeology of Berkshire* By Harold Peake (The County Archaeologies) Pp xi+260 (London Methuen and Co, Ltd, 1931) 10s 6d net

MR PEAKE introduces us to his county with an apology. He points out that it possesses no monuments of outstanding importance—only two, the White Horse of Uffington and Wayland’s Smithy, are widely known—and there are no ancient sites of exceptional interest within its borders, Silchester, by the vagaries of county boundaries, being assigned to Hampshire. Yet an area which has the Thames as one of its limits, lies next to Wiltshire, the great centre of prehistoric interest, and includes geographically, if not administratively, one of the important cities of the Roman organisation, could scarcely fail to afford material of archaeological significance. In fact, it has produced evidence bearing on every period which falls within the scope of the “County Archaeologies”, from the earliest—two eoliths are said to have been found at Boxford—to the Norman conquest, when Abingdon was a monastic centre of importance and the county was fully occupied. On certain points, indeed, its archaeological material is of considerable moment such, for example, as the epipalæolithic culture of Thatcham, and the evidence from Wittenham and the neighbourhood, which shows continuous occupation through Romano-British and Saxon times. Questions of chronology depend upon the interpretation of the evidence of the terraced gravels of the Thames, but as Mr Peake says, these must be regarded as still open. A carefully compiled gazetteer gives details, with bibliography, of all the archaeological finds in the county, arranged under parishes.

The problem of setting out a coherent record of material, so much of which consists of isolated finds, is one of considerable difficulty. Mr Peake

has solved it happily by building up a picture of the succession of events through precise detail which conforms ultimately to a pattern determined by the geographical conditions of downland, river valley, and woodland. He has thus skilfully combined the interests of the specialist and the needs of the general reader—a perennial difficulty in a series of this kind, which must do its best to make the best of both worlds.

*Science and Common Sense* By John Langdon-Davies Pp 284 (London Hamish Hamilton, Ltd, 1931) 10s 6d net

MR JOHN LANGDON-DAVIES published a year or two back an interesting and stimulating book on “Man and his Universe”, of which the thesis was that the pursuit of science through the ages was the search for God. This was carried out by a sketch of the main steps in the evolution of science, and, being connected by the one master idea, it proved valuable to many lay minds who are perplexed by the intricacies and apparent *volte-faces* in present-day science. The second volume, which is now before us, attempts the more ambitious task of a philosophic survey of the whole field and discusses the relations of science with other branches of human thought, but, unfortunately, it does not take us very far. Aiming at being philosophical, it fails from want of philosophy. Where thorough and penetrating analysis is needed, it is content to put us off with superficial antitheses which lead to the devastating conclusion, often repeated, that “Reason as a leader of men is dethroned”.

The fundamental fallacy is developed in the earlier part of the book, where it is shown that, as we are unable to reach the nature of ‘things in themselves’, the only reality within our ken is that of the relations between phenomena which are knowable only in mathematical form. These form ‘reality’ for the rest of the volume, and all other experience—ideas of love, beauty, goodness—are dismissed as ‘make-believe’. The ‘make-believe’, we are led to conclude, have no substance, because they change from age to age or man to man. As if the conclusions of science were not equally liable on their own lines to evolutionary change! A more thorough analysis would give us a goal, real for all branches, though not attainable in its fullness, which is approached on converging lines in science, morality, and aesthetics. The lame conclusion of the book is a pity, because it begins with some excellent criticism of the tools of knowledge in our senses and language. But thoroughness and comprehensiveness in thought are often to seek in English books of this kind.

*Perkin and Kipping’s Organic Chemistry* Entirely new edition by Prof F Stanley Kipping and Dr F Barry Kipping Pp xi+614+xxix (London and Edinburgh W and R Chambers, Ltd, Philadelphia J B Lippincott Co, 1931) 8s 6d

It is nearly thirty-eight years since the first publication of this now world-famous textbook. This is its third complete revision, save for a partial one in 1922. Meanwhile its influence has become so

widespread that there is almost certainly not a single chemist under forty years of age in England who has not either studied direct from it or been taught by one who has

That the book has only needed complete revision, in spite of its enormous sales, three times during four decades of organic chemical advance is an indication of the genius and scientific foresight of the original authors. Would that more textbooks were so conceived

The sad reflection that one of the original authors, who approved in 1929 of this latest complete revision, did not live to see the work completed, is partly counteracted by noting that the son of the other author now collaborates with his father in bringing up to date one of the most valuable weapons in the hands of British chemists, a good textbook is surely no less than that. On the production side there is little to criticise, save the absence of a general title page for both parts and a combined list of contents at the beginning of the book.

Some of the greatest chemical advances of our time could doubtless be traced by comparing the 1894 and 1931 editions of "Perkin and Kipping". They would comprise whole areas of organic chemistry—the structure of the sugars and higher carbohydrates, the syntheses of polypeptides, investigations into the complex structures of alkaloids, sterols, and anthocyanins, the discovery of hormones and vitamins, and the steps taken towards isolating them and certain enzymes, indeed, these constitute but a small part of the investigations that will entitle the present century to be known as the age of organic chemistry. Perkin and Kipping should beyond a peradventure take no small part of that credit

A. L. B.

*The Science Masters' Book Part 1 Physics. Part 2 Chemistry, Biology, Conversazione Experiments.* Experiments selected from the *School Science Review* by a Committee of the Science Masters' Association. Edited and arranged by G. H. J. Adlam, with the assistance of W. H. Barrett, F. Fairbrother, T. Hartley, O. H. Latter, E. J. Moore, G. N. Pingriff, V. T. Saunders, E. G. Savage, A. Vassall. Part 1 Pp. xvi + 256. Part 2 Pp. xvi + 267. (London: John Murray, 1931) 7s. 6d. net each Part

THE provision of lecture experiments to illustrate and emphasise scientific teaching is a matter of great importance, and the Science Masters' Association, in producing these two books, has succeeded in filling a marked gap in the literature. The volumes have been built up from the notes on apparatus and experiments which have appeared from time to time in the *School Science Review*. Members of the Science Masters' Association have contributed many of the experiments, and a number have been selected from the demonstrations given at the annual meetings of the Association. In this work are to be found more than four hundred experiments, distributed over the different branches of physics, chemistry, and biology. The descriptions are excellent, and a commendable feature is that, in many cases, actual figures ob-

tained in the experiments show the reader what type of accuracy can be obtained. As appendices are given some very useful notes and experiments for conversazione use, also an excellent summary entitled "First Aid in the Laboratory", as well as information concerning the obtaining of duty-free spirit. The work is admirably balanced, well produced, illustrated with many diagrams, and is to be highly commended.

*Principles of Electricity an Intermediate Text in Electricity and Magnetism.* By Prof. Leigh Page and Prof. N. I. Adams, Jr. Pp. xii + 620. (London: Chapman and Hall, Ltd., 1931) 21s. net

To any student with a good knowledge of mathematics and physics, and desirous of obtaining a sound basis of the principles of electromagnetism, this book can be recommended. It is clearly written and the symbols used are sufficiently close to the international symbols to be readily interpreted. The authors have decided that magnetic induction  $B$  and magnetic intensity  $H$  are measured in the same units (the gauss). Thus the permeability is a dimensionless ratio. If all teachers in Great Britain would agree, this would simplify teaching.

To introduce symmetry into the fundamental equations, Lorentz and Heaviside suggested a system of units which the authors call the h l system. The h l unit of charge repels an equal like charge at a distance of one centimetre away with a force of  $1/(4\pi)$  dyne. We are told that the h l system of units is used almost universally by writers on electromagnetic theory at the present time. Future students will apparently have to learn not only the electromagnetic and the electrostatic systems of units, but also the h l system. We notice that 'capacity' is used and not 'capacitance'. We have difficulty in separating what the authors mean by 'proximity effect' from what they mean by 'skin effect'.

*The Secret of the Golden Flower a Chinese Book of Life.* Translated and explained by Richard Wilhelm, with a European Commentary by C. G. Jung. Translated into English by Cary F. Baynes. Pp. ix + 151 + 11 plates. (London: Kegan Paul and Co., Ltd., 1931) 12s. 6d. net

THIS is a most welcome contribution to an understanding of Chinese spiritism. The "Golden Flower" epitomises the Chinese vision of the secret of the powers of growth latent in the psyche; while Jung's striking commentary gives a transcription of these same powers as they reveal themselves in the Western mind. In brief, the "Secret of the Golden Flower" attempts to show that the spirit must lean on science as its guide in the world of reality, and that science must turn to the spirit for the meaning of life. This main theme is developed in the Chinese version with all the poetical and mystical characteristics of Eastern wisdom. The running explanations and notes of Richard Wilhelm, who first translated this work from the Chinese, throws much light on its meaning and value.

## The Origin of the Solar System

A COPY of a paper published in the *Messenger of Mathematics* in March 1898, entitled "On the Oscillations of a Heterogeneous Compressible Liquid Sphere and the Genesis of the Moon, and on the Figure of the Moon", has been sent to the Editor of NATURE by Mr W F Sedgwick, who graduated from Trinity College, Cambridge, in the year 1894. Mr Sedgwick has also submitted the manuscript of an unsuccessful essay sent in by him for the Smith's Prize at the end of the year 1895 "On the Vibrations of a Heterogeneous Liquid Sphere, with Applications to the Solar System, and on the Elastic Solid Theory of the Earth". He states that the applications to the solar system on pp 170-171 of his published paper were based on considerations set out in much greater detail in his essay. His communications throw additional light on the history of ideas concerning the origin of the solar system. His paper has been generally overlooked in this connexion—not unnaturally, considering the somewhat distant relation between its subject and its setting—but there is no doubt of its relevance, and Sir James Jeans, in a letter to the Editor, remarks "I regret that Mr Sedgwick's work had entirely escaped my notice until my attention was recently directed to it. His theory of the origin of the solar system appears to have nothing in common with my own, except that both postulate tidal actions—of very different kinds. But I very gladly acknowledge that Mr Sedgwick's hypothesis of a tidal origin for the solar system was earlier than my own".

In view of the interest and importance of the question, the Editor considers that a general survey of the hypotheses which have been advanced to account for the existence of the planets is desirable, and he has asked me to make such a survey. Presumably the choice has fallen on one so ill-qualified because a few years ago (NATURE, April 13, 1929), in reviewing a book by the late Prof Chamberlin, it unexpectedly became my duty to comment on a controversy which had arisen in connexion therewith. Unwillingness to shirk any legitimate consequence of that review must be my excuse for accepting this further charge, but before proceeding with it there are three explanatory remarks which I wish to make.

First, this article is not to be regarded as the result of an exhaustive examination of scientific and quasi-scientific literature. It is simply an ordered account of material, most of which has been placed in my hands *ad hoc*. No claim on behalf of a hypothesis is more questionable than that of novelty. An idea which the author thinks original as likely as not proves aboriginal, and no experienced person would be unduly surprised if it transpired that modern ideas of the solar system were held by some mad precursor of Thales. If this article brings to light material so far overlooked, it will serve a useful purpose.

Secondly, no account is taken of other than published material. However strong the presump-

tion might be that ideas in a certain unpublished paper antedated similar ideas presented in a later published paper, it is still a presumption and is consequently ignored. For the same reason no attempt is made to judge of independence or otherwise of thought. The dates of presentation or publication being given, the reader can form his own opinion on such matters.

Thirdly, the material is presented without comment on its value. It is admittedly an important matter whether a criticism of, say, Laplace's nebular hypothesis, is a legitimate one or not, but it is a matter which must be left to others to decide. Similarly, it is an important matter whether a casual mention of an idea is entitled to priority over a slightly later thorough exploration of it, but that also must be left to others to decide. In brief, this article is nothing but a probably incomplete statement of facts relating to dates of publication of relevant matter.

According to Dr Harold Jeffreys (*Observatory*, 52, 173, 1929), Buffon's "Natural History" (1750) contains the suggestion that the prevalence of direct revolution among the planets might be due to the system having arisen from a grazing impact between the primitive sun and a comet. (By a 'comet', it should be said, Buffon understood something much more dense and massive than a comet as we now picture it.)

Five years later Kant, in his "Universal Natural History and Theory of the Heavens" (1755), gave another explanation, bearing strong resemblances to Laplace's later and more famous nebular hypothesis. There were, however, some important differences, among which, perhaps, the chief was that Kant imagined the angular momentum of the system to be developed during its evolution, whereas Laplace put the angular momentum among the original data.

Laplace's hypothesis, which was published in his "Exposition du système du monde" (1796), is too well known to need description. Its author does not mention Kant's work, but devotes a few lines to Buffon, whose suggestion he rejects.

On the whole, the nineteenth century was satisfied with Laplace's hypothesis, but there were some dissentients, as well as some supporters, who offered what, in view of later work, are interesting additions. Thus Croll (*Phil Mag*, May 1868, p 373, "Stellar Evolution and its Relations to Geological Time", 1889) conjectured that the original nebula which Laplace postulated might have been generated by the collision of two dark stars. Proctor ("Other Worlds than Ours", 1870), on the other hand, attacked Laplace's hypothesis and advocated the idea that the planets were built up by aggregation of meteorites. The revolt against Laplace was continued by Bickerton, who (*Trans New Zealand Inst*, 12, 193-194, 1879, and subsequent papers) substituted for the nebular hypothesis an idea, similar to Buffon's, of a grazing collision between two stars,

followed by the building up of planets by accretion of small bodies

The next idea appears to be due to Mr Sedgwick, who, in his paper in the *Messenger of Mathematics* (1898), referring to the birth of the initial planet and satellites, wrote "The initial satellite in each sub-system might be produced in the same manner as the moon on the hypothesis suggested" (that is, by tidal action of the sun coinciding in period with the natural oscillations of the primitive planets), "whilst the initial planet of the system might be caused by a similar, or different, agency in long distant periods", the "similar agency" being tidal action coinciding in period with the natural oscillations of the nebulous sun. Mr Sedgwick's earlier unpublished Smith's Prize essay cannot be considered here for reasons already stated.

On Aug 20, 1897, however, Prof T C Chamberlin, at the Toronto meeting of the British Association, gave an address on "A Group of Hypotheses bearing on Climatic Changes"—this was published as a paper in the *Journal of Geology* (5, 653-683, 1897). Chamberlin criticised the nebular hypothesis—in particular, the idea that the earth was originally molten or gaseous—and proceeded to "follow the hypothetical growth of a planet built up by the slow aggregation of small bodies which join it at low velocities and develop a minimum heat". This, so far as we can gather, was the primal germ of what later came to be known as the planetesimal hypothesis. Chamberlin, whose arguments are geological, makes no reference to the similar astronomical ideas of Proctor and Bickerton.

About three years later, Chamberlin (*Journal of Geology*, 8, 58, 1900) and, almost simultaneously, Prof F R Moulton (*Astrophysical Journal*, 11, 103, 1900) launched a more systematic attack on Laplace's hypothesis and concluded that it was definitely untenable. Chamberlin and Moulton were admittedly working in collaboration. Shortly afterwards, Chamberlin, in a paper published in the *Astrophysical Journal* (14, 17, 1901), and repeated in the *Journal of Geology* (9, 369, 1901), considered in some detail the consequences of a close approach of two stars to one another and showed that such an event might reasonably account for the existence of spiral nebulae, meteorites, and comets. No suggestion was made, however, that the solar system might have originated in this way. Moulton's help was acknowledged, and so far as objective evidence is concerned the position may be summed up by saying that at this time Chamberlin and Moulton were collaborating on problems of cosmogony, including in particular the origin of the solar system, and that the influence of two near cosmic bodies on one another was among the problems they considered. A casual remark in 1900 by Keeler (*Astrophysical Journal*, 11, 348) points to still more definite conclusions. Speaking of his studies of the spiral nebulae, he says

If the spiral is the form normally assumed by a contracting nebulous mass, the idea at once suggests itself that the solar system has been evolved from a spiral nebula, while the photographs show that the spiral nebula is not, as a rule, characterised by the

simplicity attributed to the contracting mass in the nebular hypothesis. This is a question which has already been taken up by Professor Chamberlin and Mr Moulton, of the University of Chicago.

It was not until 1904, however, that the embryonic planetesimal hypothesis actually came to birth. In the Year Book No 3 (pp 195-254) of the Carnegie Institution of Washington for that year (published in January 1905), Chamberlin, remarking that "a complete statement of the planetesimal hypothesis has not yet appeared in print", proceeded to supply one. His account reveals the hypothesis as primarily geological in character. Its central feature was the idea that the earth was built up by the aggregation of a large number of "planetesimals", the production of these bodies from solar matter drawn out by a passing star was an inessential subsidiary hypothesis. Chamberlin says

As the basis for developing the typical form of the planetesimal hypothesis, I have assumed that the parent nebula had a planetesimal organisation from the outset. To develop the hypothesis as definitely and concretely as possible, I have further chosen a special case from among those that might possibly arise, viz, the case in which the nebula is supposed to have arisen from the dispersion of a sun as a result of close approach to another large body. The case does not involve the origin of a star nor even the primary origin of the solar system, but rather its rejuvenation and the origin of a new family of planets. The general planetesimal doctrine does not stand or fall with the merits or demerits of this special phase of it, but to be of much real service in stimulating and guiding investigation, a hypothesis must be carried out into working detail so that it may be tested by its concrete and specific application to the phenomena involved, and hence the reason for developing a specific sub-hypothesis. This particular sub-hypothesis was selected for first development (1) because it postulates as simple an event as it seems possible to assign as the source of so great results, (2) because that event seems very likely to have happened, (3) because the form of the nebula supposed to arise in this way is the most common form known, the spiral, and (4) because spectroscopic observations seem at present to support the constitution assigned this class of nebulae.

From that time onwards the hypothesis has been developed in a succession of papers, its present state is described in Chamberlin's last book, "The Two Solar Families" (1928). The hypothesis of the passing star is there presented as essential to the theory, but the precise stage at which it attained that status does not concern us here.

Sir James Jeans seems first to have turned his attention to the problem in 1901. In that year he published (*Phil Trans*, A, 199, 1, abstract in *Proc Roy Soc*, 68, 454, paper received, June 15, 1901) a detailed consideration of an aspect of Laplace's hypothesis under the title "The Stability of a Spherical Nebula". At the end of this paper occurs the following passage

In conclusion, two particular cases of 'irregularities' may be referred to. If the nebula is penetrated by a wandering meteorite, at a moment at which it is close to a state of instability, the presence of the meteorite

will constitute an irregularity, and may easily result in the formation of a satellite. And if a quasi-tide is raised in the nebula by the presence of a distant mass, the same result may be produced.

The suggestion contained here made no further appearance until it had blossomed into the formal 'tidal theory'. In a paper received by the Royal Astronomical Society on Nov 3, 1916, and published in *Mem R A S*, 62, part 1, 1917, Jeans considered "the motion of tidally distorted masses, with special reference to theories of cosmogony."

In recent years [he wrote] the position of this hypothesis [Laplace's] has been challenged by speculations based ultimately upon the conception of tidal forces providing the required tendency to separation, the most complete and definite of these speculations being found in the Planetesimal Hypothesis of Chamberlin and Moulton. In the present paper I have attempted to follow up mathematically the changes in a mass of matter as the tidal forces acting on it continually increase.

As a result of the investigation the following conclusion was reached

The genesis of our solar system can very probably be attributed to tidal action, the explanation leaves room for a good deal of uncertainty in matters of detail, but does not demand anything impossible or very improbable. The evidence we have been able to obtain suggests that a system generated by tidal action might quite well have characteristics, both qualitative and quantitative, such as are observed in our system. The origin which seems most probable is not that of the planetesimal hypothesis.

Further developments—showing, like the planetesimal hypothesis, some modification of the original conjectures—are recorded by Jeans in "Theories of Cosmogony and Stellar Dynamics" (1919), Supplement to NATURE, March 1, 1924, and "Astronomy and Cosmogony" (2nd edition, 1929).

In *Ast Nach* 4308 (Jan 1, 1909), T J J See advanced the idea that the planets were not de-

tached from the primitive sun but were "captured, or added from without, and have had their orbits reduced in size and rounded up under the secular action of the nebular resisting medium" formerly pervading our solar system. The idea was further developed in "Researches on the Evolution of the Stellar Systems", vol 2, p 357, 1910.

Dr Harold Jeffreys discussed the planetesimal hypothesis in a paper in *Mon Not R A S*, December 1916 (77, 84). He considered that it was open to the objection that the planetesimals would be fused and volatilised by collisions, and so could not build up the planets by the slow aggregation postulated by Chamberlin. In *Science Progress* (July 1917) he outlined some considerations on the early history of the solar system which were developed more fully in *Mon Not R A S*, 78, 424, April 1918. Starting, like Chamberlin, from geological data, he came to the opposite conclusion, namely, that the planets were formerly liquid or gaseous. Dismissing the nebular hypothesis of their origin by an argument described as "a modification of that of Jeans", he turned his attention to the tidal theory.

This theory [says Jeffreys] forms part of the Planetesimal Hypothesis of Chamberlin and Moulton, its dynamical possibility has been proved by Jeans, and I have shown here and elsewhere [in *Science Progress*] that the system it would lead to would resemble our own in several striking features. It will be definitely adopted as a postulate in the present paper.

Jeffreys's further work is summarised in his book "The Earth" (2nd edition, 1929). The only subsequent development of significance here is the substitution (in *Mon Not R A S*, 89, 636, 731, 1929) of an actual collision for a close approach between the sun and the visiting star.

We end, therefore, where we began, the latest, like the earliest, known theory attributes our existence to the impact of another cosmic body on the primitive sun.

HERBERT DINGLE

### The History of Ergot

ERGOT has been under active scientific investigation for two generations, and has provided sociological problems for ten centuries, its secrets are now almost all laid bare, and at the moment when investigators are likely to turn aside from its study to that of other subjects, Prof Barger has come forward to write its biography.\* Usually a subject of so much interest attracts the notice of the mere collator, fortunately, ergot has not done so, and it has been left for the story to be written by a distinguished chemist, who may be congratulated on having sufficient imagination to realise how rich a story it could be. Few even of those who have worked on ergot would have guessed it.

The main importance of ergot in the past was not medicinal but as a cause of epidemic disease, instead of a healing draught, it was a scourge.

\* Ergot and Ergotism: a Monograph based on the Dohme Lectures delivered in Johns Hopkins University, Baltimore. By Prof George Barger. Pp xvi+279+6 plates (London and Edinburgh Gurney and Jackson, 1931) 15s net.

Strange as it may seem to us in Great Britain, "rye is still the chief cereal in a large belt of Europe extending from Holland across Northern Germany, Czecho-Slovakia, Austria, Poland, and Central Russia", and in Poland, for example, four times more rye is eaten than wheat. From the ergot present in the rye have come the many epidemics of ergotism.

Ergotism occurs in two forms, known respectively as gangrenous and convulsive, in the first form the symptoms are due to the effect of ergot on the blood vessels, as a result of which the blood supply to the extremities is cut off, so that gangrene occurs and the limb drops off, loss of the leg below the knee is common. Convulsive ergotism, on the other hand, is not an affection of the blood vessels, but of the central nervous system, it is characterised by the appearance of areas of degeneration in the spinal cord, and the symptoms are convulsive seizures.

The distribution of the two forms of ergotism has long been a mystery, which Prof Barger has now solved by the light of the recent work of E Mellanby in Sheffield. For example, about 1770 there was an epidemic of gangrenous ergotism in Sologne on the left bank of the Rhine, while in Hanover on the right bank there was an epidemic of convulsive ergotism. Why should there have been so sharp a difference in the symptoms in the two localities? Now Mellanby has shown that convulsive ergotism is readily produced in dogs which are given one or two grams of ergot daily, provided that the diet is free from vitamin A, but the same amount of ergot produces no harmful effect if vitamin A is added to the diet. Prof Barger points out that the difference in the 1770 epidemics in Sologne and Hanover fits in admirably with this work, Sologne was a dairy-farming district where the inhabitants had milk and butter, the vitamin A present in the diet prevented the appearance of nervous symptoms. In Hanover, on the other hand, the soil was very poor and unable to support cattle, so that the peasants had little save rye to eat, in consequence the nervous type of ergotism appeared.

Records of gangrenous ergotism go back to A.D. 857, when the "Annales Xantenses" state that a great plague of swollen blisters consumed the people by a loathsome rot, so that their limbs were loosened and fell off before death. The early approach of the disease is marked by a feeling of intense heat in the part affected, and this was responsible for the name 'holy fire', which during the twelfth century became associated with St. Anthony, when many sufferers began to visit the saint's relics preserved in an abbey near Vienne in Dauphiné. There was a hospital attached to the abbey, and the sick either died within seven days of their arrival or were 'miraculously' restored to health by the wholesome food they received there. The historical details which Prof Barger has collected make fascinating reading of a kind which is only too rare in modern scientific monographs, we learn how ergotism even prevented a military campaign in Russia in 1723.

The history of the introduction of ergot into medicine is also surprising, the earliest mention of its use as a drug is in the 1582 edition of Adam

Lonicer's "Kreuterbuch", but its real entry into official medicine took place in the United States. "In the Medical Repository of New York there appeared in 1808 an 'Account of the Pulvis parturiens, a Remedy for quickening Child birth', in the form of a letter from Dr John Stearns of Saratoga county to Mr S Akerly." The method of administration was either in decoction or in powder. "It expedites lingering parturition and saves to the accoucheur a considerable portion of time."

Prof Barger's monograph includes also botanical, chemical, pharmacological and clinical, pharmaceutical, and forensic sections. While Tanret in 1875 was the first to isolate one of the ergot alkaloids in crystalline form, this substance, ergotamine, is inactive, and Prof Barger himself, together with Dr F H Carr, was responsible in 1906 for the isolation of ergotoxine, which is almost certainly the more important of the two active alkaloids. All four alkaloids, ergotamine, ergotoxine, ergotamine, and ergotaminine, have recently been obtained in crystalline form by S Smith and G M Timmis, and are known to be separate chemical individuals. Ergotamine has the formula  $C_{35}H_{39}O_5H_5$ , while ergotamine and ergotaminine are isomers having the formula  $C_{33}H_{35}O_5N_5$ . Only the formula of ergotoxine remains in doubt, the probability being that it is also isomeric with ergotamine. There remains the puzzle of the occurrence of ergotamine, the active alkaloid isolated by Stoll, for no other worker has obtained ergotamine from ergot of rye, the claims of Forst to have done so being open to doubt. Smith and Timmis readily obtained ergotamine from the ergot of *Festuca elatior*, but failed to do so from any of the many samples of ergot of rye which they examined. Stoll's statement that ergotamine is present in ergot of rye is, therefore, lacking in confirmation.

Prof Barger's book, in its completeness and in the care taken in its presentation, is a work of art, it is a model which should inspire others, particularly those interested in pharmaceutical science, to attempt to do the same for other drugs. One imagines that among the pharmacists the book has created a sensation, which will provide them with eager discussion for some months to come.

## Obituary

PROF. E. WILSON

THE sudden death on Feb 17 of Prof Ernest Wilson, emeritus professor of electrical engineering and fellow of King's College, London, came as a shock to his many friends and caused a widespread feeling of loss in scientific and engineering circles. Though frail in appearance, he possessed a vitality which was the envy of his numerous friends, together with an engaging personality and a devotion to duty exhibiting the utmost selflessness, which endeared him to students and all with whom he came in contact.

Born in Lincolnshire, on Nov 25, 1863, he joined the works of Messrs. Greenwood and Batley,

Leeds, where he served his time as a six-o'clock lad, learning some of life's lessons, as well as laying a solid foundation for his life's work. It is interesting to note that while at this works he was engaged on the construction of the first Brush machine and the first Ferranti alternator made in England.

Making the most of his opportunities and attending technical classes at the Yorkshire College, Wilson secured a Whitworth scholarship, which enabled him to proceed to Germany, 1886-87, and take up further studies and gain engineering experience. During his study of electro-technology in Germany, he assisted Prof Kohlrausch

in making elaborate tests on an early Lahmeyer dynamo with the object of verifying Dr Frolich's theory of the dynamo

Afterwards, Wilson became a draughtsman in the Woolwich works of Messrs Siemens Brothers, where he was largely responsible for much of the pioneer electrical work and progress of that firm. While at Woolwich, he attended evening classes at Finsbury Technical College, where he came under the influence of John Perry and Silvanus Thompson. He was appointed assistant to Dr John Hopkinson at King's College in 1890, and, following the tragic death of Hopkinson, in 1898 he was appointed to the chair of electrical engineering, from which he retired in 1930, after forty years of devoted service as a teacher and friend of hundreds of students

Early in his career Wilson encountered a multitude of problems which then confronted electrical engineers, such as the design of the electric motors to be used on the three-wire system for the first locomotives for the City and South London Tube Railway. This experience led him to write "Electrical Traction", published by Edward Arnold in 1897. The second edition of this book, long recognised as a standard work on the subject, was written in collaboration with Mr F Lydall and appeared as two volumes in 1907.

Although engineers are slow, as a rule, to take up the pen, Wilson proved to be an exception, for he was a prolific writer. From 1892 on, he contributed no less than eighty papers of his own, and about thirty of joint authorship, to the *Philosophical Transactions* and *Proceedings of the Royal Society*, *Proceedings of the Physical Society*, numerous technical journals, and to the British Association. His first paper to appear in the *Journal of the Institution of Electrical Engineers*, vol 26, 1897, dealt with the "Relative Size, Weight, and Price of Dynamo Electric Machines", and his first contribution to *Engineering*, in 1891, dealt with the electric lighting of the Royal Naval Exhibition (1891), where his control switch for the manipulation of searchlights was shown in use.

Besides assisting in joint experimental work with Hopkinson, Wilson engaged in many researches, he worked in the fields of alternating current instruments, radio telegraphy in its early phases, the magnetic properties of iron and various alloys, and especially studied the properties of aluminium and its alloys with reference to conductivity and deterioration. He published a number of papers on magnetic shielding and the susceptibility of feebly magnetic materials. One of his earliest inventions was that of the laminated-field single and polyphase alternating-current commutator motor in 1888 (British Patent 18,525), and his original machine is to be seen at the Science Museum, South Kensington. On being requested to do so by Sir William Preece, he carried out the first tests of Marconi's wireless apparatus on the terrace at King's College, and, so far as the writer is aware, gave a favourable report on the possibilities of the new device.

The Institution of Electrical Engineers awarded

Wilson the Kelvin Premium in 1921, and, so recently as last year, a premium for his paper, "The Electrical Conductivity and Tensile Properties of Light Magnesium-Aluminium Alloys as affected by Atmospheric Exposure". He was elected a member of the Council of the Institution in 1929, thereafter taking an active part in the proceedings of its committees.

Wilson took a leading part in the development of the faculty of engineering of the University of London, and was a member of the various boards of the University until his retirement.

Possessing a retiring and modest nature, Wilson made little effort to bring himself or his work before the notice of the public or even of the engineering profession, but, on the other hand, few teachers could claim so large a circle of friends or so sincere a regard as that in which he was held. He had known many of the pioneers of electrical engineering and he had an almost unrivalled store of information about early experiments and the whereabouts of original pieces of apparatus, and his advice was always sought whenever such information was wanted.

Since his retirement from the William Siemens University chair of electrical engineering at King's College, London, in 1930, Wilson devoted himself whole-heartedly to the arduous task of advising engineer students, both past and present, as to their best way of securing employment. In this he was highly successful, and last year he assisted so many as one hundred young men to obtain posts in engineering work. Wilson leaves a widow, a son, and a daughter.

J K C-S

#### DR W D DYE, F R S

AFTER a very short attack of pneumonia following influenza, there passed away on Feb 18, at the early age of forty-four years, an unusually brilliant experimenter in the person of Dr W D Dye. After being educated at Portsmouth and the City and Guilds Technical College, Dye was appointed a student assistant at the National Physical Laboratory. At that time, Mr Albert Campbell had completed his well-known standard of mutual inductance and was engaged on very precise comparisons of resistance with mutual inductance. Other work engaging Campbell's attention was an evaluation of the ohm by an alternating current method, and a study of experimental methods for the measurement of the length of wireless waves.

In this atmosphere of high precision alternating current measurement, Dr Dye soon became at home. He noted, with some surprise, Mr Albert Campbell's love of making, with his own hands, small and delicate instruments like thermocouples and galvanometer suspensions, and quickly acquired similar skill. Indeed, in this direction, he delighted to do what many others thought to be impossible. He made up his mind very quickly, and when an experiment failed to give results of immediate service, he abandoned it rather than modify small details. Alternative methods for achieving results came to his mind very quickly, and not infrequently he would scrap one method

and have an alternative one worked out within a few hours

After the War, Dr Dye succeeded Mr F E Smith, now Sir Frank Smith, as head of the Electrical Standards Division, and established his reputation for highly accurate work in the measurements he carried out on the primary electrical standards and units, including standards of inductance and capacity. He devised a new method for accurate measurement of the vertical component of the earth's magnetic field, and the apparatus he constructed for this purpose is now the principal instrument in regular use for absolute measurements at the Abinger Magnetic Observatory. More recently he had devoted himself to the development of new methods of time measurement for precise standardisation of radio frequency, and had already achieved results of a very high order, using a specially controlled tuning-fork and a quartz oscillator. He was a member of the Radio Research Board and of the British National Committee of the Union Radio-Scientifique Internationale, of which he was secretary, and at the Congresses at Washington, Brussels, and, last year, at Copenhagen, he acted as chairman of the Commission on Radio Standards. He was elected a fellow of the Royal Society in 1928, and was a member of the Council of the Physical Society

#### SIR ARTHUR DUCKHAM, G B E, K C B

THE death of Sir Arthur Duckham, which occurred with tragic suddenness on Feb 14, is a great loss to the nation. He stood in the forefront of British industries and, at the age of fifty-two years, in the fullness of his powers, seemed destined to play a great part in the campaign that lies before our industrial leaders. Trained as an engineer under the enlightened regime of Sir George Livesey at the South Metropolitan Gas Company's works, Arthur Duckham evinced at an early age the inventive skill, enterprise, and energy which bespoke a great future. In conjunction with Col H W Woodall at Bournemouth, he brought to success the well-known Woodall-Duckham process for the continuous carbonisation of coal in vertical retorts. From this achievement he passed to other work connected with furnace construction and carbonisation, and built up the great organisation

of Woodall-Duckham enterprises, of which he was the leading spirit.

Duckham's labours extended widely beyond this commercial enterprise. Early in the War he was brought into action in connexion with munitions supply and, by his exceptional gifts, soon attained a leading position in this exacting and vital work. His services were recognised by conferment of K C B in 1917. He was a member of the Sankey Coal Commission in 1919 and, in an individual report, favoured State ownership of mineral rights but not of mines. In 1928 he spent seven months in Australia as chief of a small commission of English industrialists appointed to advise on trade opportunities with that country. Further recognition of his public services was marked by the conferment of G B E in 1929.

Duckham had a full appreciation of the part to be played by science in modern industry. Without extended formal scientific training, he had the scientific instinct and outlook. In his own business he had an elaborate and highly efficient scientific intelligence service which secured all necessary aid for his various enterprises. He was ever ready to plead the cause of science, and he had occupied the presidential chair of the Institution of Chemical Engineers and the Society of British Gas Industries. He was president-designate of the Federation of British Industries for 1932.

Sir Arthur Duckham was endowed with qualities of character and temperament which, in all walks of life, made an instant appeal and secured for him a quite exceptional measure of regard. His loss will be felt as a personal bereavement throughout a very large circle.

#### WE regret to announce the following deaths

Sir Frederick William Andrewes, F R S, emeritus professor of pathology in the University of London, a pioneer of bacteriology in Great Britain, on Feb 24, aged seventy-two years.

Dr George Claridge Druce, F R S, curator of the Fielding Herbarium in the University of Oxford, on Feb 29, aged eighty-one years.

General G Ferrié, formerly president of the Committee on Longitudes of the International Astronomical Union, on Feb 16, aged sixty-three years.

### News and Views

#### Prof A. W. Williamson and Japanese Development

MUCH attention is being given at present to affairs in the Far East, in connexion with which it is of interest to recall the pioneer efforts of nearly seventy years ago of Prof Alexander W. Williamson, F R S, the distinguished chemist, to enable Japanese youth of high rank to obtain a knowledge of European methods in education, the arts and sciences, commerce, and manufactures. In association with him was a small band of men, inspired by his enthusiasm and example. Williamson was born at Wandsworth in 1824, and he died in 1904. Educated mostly abroad, he was a

pupil of Gmelin, at Heidelberg, and Liebig, at Giessen. In 1849 he was elected professor of practical chemistry at University College, London, with which the chair of general chemistry was later (1855) combined; he remained in the service of the College for thirty-nine years. Williamson was foreign secretary of the Royal Society from 1873 until 1890, and a Royal medallist of that body. On two occasions he was chosen president of the Chemical Society.

THE opening for Williamson's scheme came in 1863, when he received, through a London merchant having trading connexions in the Far East, an offer to send

him five Japanese youths to be housed and started in educational courses akin to English ideas and outlook. Thereupon Williamson undertook the necessary supervision, and he discharged his responsibilities thoroughly. It is sufficient to mention the after careers of these students of English methods to show this. One, who became the Marquis Ito, framed, in course of time, his country's constitution, a second, afterwards Count Inouye, aroused and developed commerce, a third, Viscount Inouye, inaugurated the Japanese railway system, a fourth, Viscount Yamao, became the first Minister of Public Works, and initiated a scheme of technological training, assisted by workers drawn from British sources. In all this early planning Williamson had a share, through his disinterested activity. The first contingent of youths was followed by a party of sixteen from Tokyo, sent by the Prince of Satsuma, also placed under Williamson's watchful eye. Among these were Mori, Yoshima, and Sameshima. Finally, just over half a century ago (1880), we find Williamson engaged in a research with Sakurai, the Japanese chemist, and others of his nationality.

#### Imported Scientific Films and Museum Specimens

By the Finance Act of 1925, a customs duty of 33½ per cent was placed upon films imported into Great Britain. During the debate on the Finance Act of 1928, Capt Ian Fraser, M.P., moved an amendment exempting from duty "cinematograph films . . . certified by the Royal Society of London for promoting Natural Knowledge to be solely an illustration of scientific investigation for exhibition before members of a recognised scientific body and imported only for the purpose of such exhibition free of charge". This amendment was accepted, and proved to be a small but much appreciated boon to scientific workers and others, who obviously benefit by the free international exchange of films recording their investigations. The new Import Duties Bill did not include such films in its list of imports exempt from duty, and Capt Fraser put down an amendment the object of which was to retain the privilege. This amendment has now been taken over by the Chancellor of the Exchequer as an official amendment, and was incorporated in the Bill on report stage on Feb 25. In a letter in the *Times* of Feb 27, Sir Henry Wellcome refers to the position of material for exhibition in museums. A clause has been added to the Import Duties Bill exempting such material when it is more than a hundred years old, but this will not cover natural history, ethnographical, and other specimens required by research workers. The Museums Association, in a letter from its honorary secretary, Mr D W. Herdman, has endorsed Sir Henry Wellcome's statement, adding that its views have already been communicated to the Chancellor of the Exchequer. Museum material is clearly on the same footing as printed books, and we hope that it will be possible similarly to exempt it from import duty.

#### Prof C. V. Boys's Apparatus at the Science Museum

PROF C V BOYS has recently presented to the Science Museum, South Kensington, some very interest-

ing examples of his early experimental work. His use of quartz is shown in one case, where the bow which he employed in 1889 in the preparation of quartz fibres by the well-known 'bow-and-arrow' method is exhibited, together with examples of arrows used with it. Several of the fibres made by him in this way are exhibited, as well as the first quartz bulb ever blown. Soon after his successful production of quartz fibres, Prof Boys utilised this material in an attempt to determine the constant of gravitation with a modified form of the Cavendish apparatus. He showed that increase of sensitivity could be accompanied by a considerable reduction in size, thus greatly reducing convection troubles. A small experimental apparatus made in 1889 served to demonstrate that consistent and accurate results could be obtained in this way, and as a result of the experience thus gained, a somewhat larger apparatus was made and used between 1889 and 1894 for the determination of the gravitational constant. Both instruments are now exhibited together, and form a permanent record of Boys's classical determination of this most important constant. In addition to the above, the following pieces of apparatus due to Prof Boys are also on exhibition: the original experimental radio-micrometer, a portion of a new form of difference engine, and two electrometers, both dating from about 1891.

#### Scientific Research at the British Museum

By the establishment in April 1931 of the Research Laboratory at the British Museum as a permanent institution under the control of the Trustees, the experimental stage of the undertaking, which had been continued by the Treasury and the Department of Scientific and Industrial Research for no less than eleven years, was brought to a successful conclusion. In a paper read before the Royal Society of Arts on Feb 24, the Director of Scientific Research, Dr Alexander Scott, indicated the nature and variety of the work carried out in his laboratory and described some of the results which have been obtained. In discovering the best means of restoring and preserving museum objects, it is essential first to learn all that is possible regarding the previous history of each specimen, neglect of this essential has, in the past, led to many failures and has earned scientific men an evil reputation. The establishment of the research department on a permanent basis, however, is clear proof that the custodians of the nation's treasures have confidence in the methods which have been devised with so much care and applied with so much success.

#### Restoration and Preservation in Museums

DR SCOTT referred to the disintegration of stone objects arising from the crystallisation of salts contained in the porous material, and to the extraction of the salts by means of wet paper pulp, salts are also removed from fragile brick tablets by first applying a celluloid coating, and then diffusing the salts into distilled water. Stains on old manuscripts can frequently be removed by the application of pyridine, and brown marks on water-colour pictures by the application of a solution of chloramine-T. The treatment of 'bronze

disease', a condition due to the presence of chlorine, by soaking in sodium sesquicarbonate solution followed by copious washing will often remove all the chlorine without attacking the patina, whilst in aggravated cases, soaking in citric acid solution or the use of an electrolytic process may be necessary. Fourteenth century glass from Wells Cathedral was found to be coated with material derived from the combined action of an impalpable powder arising from the limestone floor and sulphuric acid provided by the combustion of gas. Other problems the successful solutions of which were described by Dr Scott included the corrosion of a silver chalice, the unrolling of a manuscript on fragile leather, and the cleaning of marble busts.

#### Chemical and Photochemical Reactivity

ON Dec 17, 1931, the Chemical Society devoted an ordinary scientific meeting to a discussion on the critical increment of homogeneous reactions. It was immediately apparent that the material then presented and the observations then offered should be put on permanent record in an accessible form, and this has since been done by the publication of a separate pamphlet (1s 6d) bearing the imprint of the Society and following the form of its *Journal*. The discussion was opened by Mr C. N. Hinshelwood, whose subject was the energy of activation of chemical reactions. The magnitude and nature of activation energy, catalytic phenomena, and the contributions of quantum mechanics to the problem were among the matters considered. Mr E. J. Bowen followed with a paper on photochemistry and chemical reactivity, referring to photosensitisation, the phenomenon of 'predissociation' discovered by Henri, and the direct reaction of excited and normal molecules. Prof. A. J. Allmand's contribution dealt with the variation of quantum efficiency with wave-length in photochemical reactions, five different types of effect are distinguished, and their incidence in affecting the quantum yield was examined. Prof. E. K. Rideal discussed transition reactions, while Dr F. G. Soper gave an account of researches on the effect of solvents on reaction velocity. Dr. T. Iredale communicated a short contribution dealing with the heat of activation of hydrogen iodide. In the spontaneous discussion which followed, Dr R. G. W. Norrish, Mr C. R. Bailey, Prof. Allmand, Mr H. W. Thompson, and Mr Hinshelwood took part. Their observations, together with the full text of the principal contributions, are to be found in the publication already mentioned.

#### Preservation of the Fauna of the Empire

IN a short address at the general meeting of the Society for the Preservation of the Fauna of the Empire, the chairman, Sir Peter Chalmers Mitchell, made a strong appeal for the consolidation of the position in regard to animal reserves within the Empire. At present the continued existence of faunal reserves depends upon the goodwill of individual governments or individual parliaments. The discovery of mineral deposits, the demand for timber, and other possible eventualities, may lead to particular

reserves being thrown open to traffic or trade, with disastrous effects to the animal population, which cannot be herded into new areas at the will of man. What is needed for the permanent protection of those faunas, which are rapidly becoming relic faunas, is the raising of the status of their native territory in certain cases from temporary reserves to permanent national parks. The Society, which since its foundation has worked so strenuously on behalf of the Empire's threatened animals, has often appealed, with reasoned arguments founded upon the reports of its own observers, to the Colonial Office, but so far without success. The alteration would involve no extra expenditure, ultimately, indeed, the national parks by proper administration would bring in a certain amount of revenue, the surplus earned by the Game Department of Kenya, under strictly regulated conditions, was £15,022 in 1930. At present their creation would cost nothing, and would mean permanent security for the animals and plants in the reserved regions.

WE strongly commend the campaign which the Society has launched for the spread of news relating to wild life. A short time ago we read in a northern newspaper an account of life in the forests of British Guiana, and the article was to be followed in the course of a few days by a lecture. It is excellent propaganda, the educational value of which must be appreciated by everyone interested in Nature and its preservation. The Society has in all 867 members; it deserves and ought to have many more. May we suggest that somewhere, say on the blank cover of the *Journal*, from the December number of which we have quoted, a note should appear of the conditions of membership and of the amount of the annual subscription.

#### Frequency Range of Broadcast Receivers

IN opening a discussion on the selectivity of broadcast receivers at the Institution of Electrical Engineers on Feb 24, Prof. C. L. Fortescue said that as the apparatus tested becomes more and more sensitive, components of higher and higher frequencies are found in it. The female voice is known to have components having frequencies so high as 10,000, and footfalls, hand-clapping, and the operation of typewriters are observed to have components of frequencies approaching 16,000. In broadcast transmitters provision is not usually made for such a wide range, and nearly every receiver has a much more limited range. A lower frequency limit of 50 and an upper limit of 5000 are usually considered to give good results. In the production of talking films, the audio-frequency output is, perhaps, subjected to the most careful scrutiny. In this case there is a noticeable tendency to try to get a full response up to a frequency of 10,000.

THE problem of getting uniformity of response over the whole audible range is more difficult. A highly trained observer detects, at particular frequencies, increases or diminutions in the loudness which the ordinary person does not notice. 'Musical' people are sometimes even the least critical of all in this

respect, owing to their peculiar power of imagining all the missing parts, just as in an ordinary telephone conversation the listener himself occasionally provides as much as fifty per cent of the intelligibility. It was mentioned that there is a good deal of evidence to show that many receivers accept high-frequency energy over a far wider range of frequency than is necessary. The result is that they suffer from serious interference, as the waves of transmissions on neighbouring frequencies and the programmes they carry are also heard. It would obviously be better to limit the high-frequency range. The question of whether the average purchaser of a broadcast receiver can be entrusted to get the best results from a sharply tuned high-frequency circuit is one that can only be settled by statistics.

#### Fisheries of the Thames Estuary

IN a note in *NATURE* of May 11, 1927, attention was directed to the unpublished reports of Dr James Murie on the Thames Estuary fisheries. Before his death in 1925, Dr Murie had published the first part of his "Report on the Fisheries of the Thames Estuary", containing Sections 1 to 3 and the greater part of Section 4. The second part, consisting of a large folio volume now in the Southend Public Library, was not published. Part of this is in galley proof, but the sixth section is in manuscript, and was written probably between 1895 and 1912. It was found in 1926 in an outhouse of Dr Murie's cottage at Leigh, and consisted of a sodden mass of paper. The sheets were carefully separated, dried, and transcribed by the Borough Librarian, Mr Pollitt, and a digest of this unpublished section is embodied in a long article by Mr A. Laurence Wells, published in the *Southend Standard* (Jan. 7 and 14, 1931), entitled "Special Thames Estuary Fisheries". The matter is full of interest and covers a wide field. It consists mainly of detailed notes on the various fisheries in the Thames Estuary, especially those relating to the Leigh fishermen, and embraces the history of many of the older industries and the methods employed, both ancient and modern. These carefully collected data about each individual fishery are of historical value. Many of the methods are now obsolete, but most of the fisheries themselves are still flourishing.

WHITEBAITING is a comparatively recent industry among the Leigh fishermen. Some two hundred years ago it was practised up the river beyond Blackwall, but pollution of the water has driven the whitebait more to the Thames mouth, where the fishing is principally carried on. At first they fished only in spring, then in the original season from February to August, now they fish throughout the year. Shrimping, on the other hand, is an industry of long standing, begun about a hundred years ago. Starfish dredging used to be profitable, now it is almost extinct. The five-finger star is a great enemy of the oyster, and in dredging for them the fishermen not only helped the oyster but also utilised the starfish by selling them to the farmer for manure. Now, however, owing to chemical manure, the farmer no longer wants them. Other enemies which are much dreaded both by the

whitebaiters and the shrimpers are the jelly-fishes and ctenophores, known by them as 'flat gall' and 'nut gall'. These come swarming from the sea during April and May, clogging the nets so that a continual and wearisome sorting is necessary. This manuscript is an important addition to the literature concerning the Thames Estuary fisheries, and all workers on the subject are indebted to those who have made it available to the public. Although containing about 22,000 words, it is obviously unfinished, for further sections were indicated consisting of notes on many other specialised forms of fishing.

#### Geodesy in India

THE Geodetic Report of the Survey of India, vol. 6, deals with the very varied and extensive work done during the period Oct. 1929–Sept. 1930. A regular latitude variation programme has been started, supplementing the regular longitude observations, and in due course will throw light on the existence or otherwise of crustal drift. The irregularities in the longitude results remain unexpectedly large. To improve the time-keeping, a Shortt clock has been obtained. The form of the geoid in India and the gravity work have now brought irrefutable confirmation of Burrard's Hidden Range, which at first was inferred from rather scanty deflexion data; the Hidden Range is found to be flanked on both sides by troughs. Again, the levelling results obtained in Bengal during the last seventy years have been discussed. The closing errors of the various circuits are found to be surprisingly large, much greater than should occur in the class of levelling explained. It appears that they can be simply and naturally explained by supposing that real changes of level have occurred. Parts of the alluvial plains of northern Bengal and Bihar seem to have been rising at the rate of one foot in twenty years; tidal records indicate that Calcutta is not sinking, so that the country farther north is presumed to be rising. Further, tidal predictions for the Indian Ocean have been published in a new and cheap form of greatly increased scope, on lines similar to those of the Admiralty Tide Tables.

#### British Museum (Natural History) Acquisitions

AMONG the recent acquisitions by the Department of Zoology are two important gifts from the Rowland Ward trustees, namely, the skull and horns of a fine specimen of the giant sable antelope from Angola and a group of the little ant-eater from northern Brazil. A valuable collection of birds has been received from Mr R. E. Moreau, secretary and librarian of the East African Agricultural Research Station at Amani, Tanganyika Territory. This collection, which was made by the aid of a grant from the Godman Exploration Fund, consists of some four hundred specimens belonging to about two hundred species, of which eight appear to be new to science. Acquisitions in the Department of Minerals include a large block of granite showing quartz-porphyry and a vein of apatite, from Penryn, Cornwall, presented by Mr. Ernest H. Davison, samples of platinum ore from Southern Rhodesia, presented by the director, Geological Survey of Southern Rhodesia, and specimens from

other regions. A model of the largest platinum nugget found in the Urals and crystals of sylvanite (sulpho-vanadate of copper) from Utah have been purchased. The herbarium of the Royal Botanical Society of London has been presented by the Council to the Department of Botany. A valuable collection of about eleven thousand European mosses has been presented by the Rev P G Rhodes, and Mrs T G Elliott has presented about four hundred specimens of Ceylon ferns collected by her father, the late Rev E N Freeman. The latter is of special interest as being the first large collection of localised Ceylon ferns received by the Department.

#### Hippophagy in Ancient Palestine

AN interim report from Sir Flinders Petrie on his excavations at Tell-el-Ajjul in southern Palestine, in the *Times* of Feb 24, dwells on the significance of the exploration of this area for the history of the Hyksos domination in Egypt and Palestine. "The south of Palestine", it is said, "proves to be the best source for understanding this great catastrophe of ancient times." The date of the city is now fixed by scarabs of Apepa I and the names of other Hyksos kings. The work of this season has brought to light a new custom. It will be remembered that last year the remains of a horse were discovered in one of the large pit-graves on the plain below the tell. The horse was disposed in the centre, while the bodies of the members of the family lay on shelves around the pit. Now the remains of a horse have been discovered which had evidently been sacrificed and its body buried under the foundations of a large building. Near by an oven had been built for the purpose of cooking the thigh and shoulders of the victim for a feast, while another horse had been completely cut up and the bones left on the ground after it had been eaten. Sir Flinders Petrie adds the interesting comment that no other example of hippophagy has been found in the east, and in the west the practice is not known later than the stone age.

#### Prof W. E. Garner

THE course of lectures on detonating substances which was to have been given at the Royal Institution on March 1, 8, and 15 by Prof W E Garner, Leverhulme professor of physical chemistry in the University of Bristol, has been postponed owing to an accident to him. Prof Garner has been engaged for some time in a research on solid explosive substances. On Thursday, Feb 25, when he was about to remove a crystal of pure lead azide from a cardboard pill-box containing about 5 mgm of the material, as he raised the cover of the box with his right hand, the material exploded. Two of his fingers were seriously damaged and his left hand received lesser injuries. We are glad to learn that he is making very satisfactory progress.

#### French Exploratory Voyages

A USEFUL chart of the world showing all the great French voyages of exploration from the fifteenth to the early nineteenth century is included in the issue of *La Géographie* for July-August 1931. The

chart, originally prepared by M H Roussilhe and L Bergelin for the Exposition Internationale d'Anvers in 1930, is based on the original itineraries and charts of the voyages concerned, and though on a comparatively small scale, is remarkably clear. An old-world appearance is given to it by various reproductions of vessels of the periods of different voyages, taken from contemporary sources and suitably placed on the oceans.

#### New Land Speed Records

ON Feb 24, at Daytona, Florida, Sir Malcolm Campbell set up a new record for land speed in his car *Blue Bird*. On two runs, northwards and southwards respectively, over a measured mile, his average time gave a speed of 253.968 miles an hour, thus beating his own record made last year at the same place and in the same car by about eight miles an hour. Sir Malcolm made a further attempt on Feb 26, but his speed over the measured mile was returned as 251.748 miles an hour. His average for five miles, however, worked out at 242.751 miles an hour, thus beating his own previous record for this distance by more than thirty miles an hour. Sir Malcolm's car *Blue Bird* had been fitted with a new and more powerful Napier engine of approximately 1500 h p.

#### Muslim Association for the Advancement of Science

THE objects of this Association, which was inaugurated at Aligarh about a year ago, are to stimulate research work amongst Mohammedans by means of grants in aid of special laboratory apparatus, research materials, and laboratory assistance. The Association is undertaking the publication of specialised memoirs by distinguished investigators in its *Proceedings*, and its constitution permits the creation of research professorships and visiting lectureships as soon as sufficient funds become available. Nawab Masood Jung, vice-chancellor, and Dr R F Hunter, the present holder of the Nizam chair of chemistry in the Aligarh Muslim University, are the first president and vice-president respectively, but the Association's constitution has now been extended to include representation on its council from British India, Hyderabad, and Egypt.

#### The Hayden Memorial Gold Medal

IT is announced that the Academy of Natural Sciences of Philadelphia has awarded the Hayden Memorial Gold Medal for 1932 to Dr Reginald Aldworth Daly, Sturgis-Hooper professor of geology in Harvard University. This is the outstanding American award for pre-eminence in geological and palaeontological research. Prof Daly's work chiefly involves the study of igneous rocks, their genesis, and the mechanics of their intrusion into the mountains of the earth. Other of his outstanding contributions to geology are his glacial-control theory of coral reefs, his work on the eustatic shift of oceanic level, and his researches on the constitution of the earth. He has presented many of his ideas in popular form in his book, "Our Mobile Earth" (1926). The Hayden award, which is made every three years, was founded in 1888 by Mrs Emma W Hayden, of Philadelphia, as

a memorial to her husband, Dr Ferdinand V Hayden, director of the United States Geological and Geographical Survey in the early days of that organisation

#### Botanic Gardens in South Africa

IN Part 17 of the *Journal of the Botanical Society of South Africa* (1931) is published an excerpt from the report written by Sir Arthur Hill to the Union Government after his tour in South Africa in 1929, which was referred to in NATURE of Feb 7, 1931, p 217. The report states that at present, owing to lack of funds, the Director of the Kirstenbosch Botanic Garden is working single-handed and the garden staff is inadequate. This refers to 1929, and in the present *Journal* the Gardens have to report a ten per cent reduction of the Government grant which they share in common with other State-aided institutions. On the whole, the moment scarcely seems propitious for the consideration of Sir Arthur Hill's suggestion that South Africa should try to maintain three botanic gardens, with the development of a sub-tropical botanic garden at Durban and a botanic garden with arboretum at Pretoria. It is good to see that the body of supporters for the Kirstenbosch gardens, provided by the Botanical Society of South Africa, continues steadily to grow in numbers. In this same report Sir Arthur Hill presses for the policy of making Table Mountain into a Nature reserve, and it is good to learn that action has now been taken by the Administrator of the Cape Province which gives complete legal protection to the flora and fauna of the Mountain.

#### Biology and Quantum Theory

PROF NIELS BOHR, of Copenhagen, has brought together a collection of articles dealing in a rather general way with modern physics, under the title "Atomtheorie und Naturbeschreibung" (Berlin Julius Springer, 1931. 5 60 gold marks). Reference is made in several of the articles to the question of the relation between the development of quantum theory and the formulation of the fundamental problems of biology. The point of view which is taken is that a consideration of the new ideas and methods of physics, often essentially foreign to ordinary conceptions and experience, may indicate how the discussion of the place of living organisms in our scheme of things should be approached. Prof Bohr directs attention to the existence of a natural limit to the investigation of life in the inevitable death of an organism which is subjected to a complete physical investigation of its atomic constitution. A recognition of the importance of such matters is perhaps becoming rather general, as we find Dr P. A. M. Dirac grouping the problem of life with the relativistic formulation of quantum mechanics and the nature of atomic nuclei—as a "more difficult" problem—in the introduction to a paper on quantised singularities in the electromagnetic field, in the *Proceedings of the Royal Society* for last September, but it can scarcely be irrelevant to refer here also to Samuel Butler's ingenious treatment of a similar topic in "The Book of the Machines", sixty years ago, in "Erewhon".

No 3253, VOL 129]

#### Announcements

By an order of the Committee of Privy Council, Mr W. S. Morrison, M.P., has been appointed a member of the Medical Research Council, on the retirement of Major A. G. Church.

PROF G. ELLIOT SMITH, professor of anatomy in University College, London, has been given the honorary degree of M.D. by the Egyptian University, Cairo, on the occasion of its first convocation, held on Feb 27. Prof Elliot Smith was at one time professor of anatomy in the Government Medical School, Cairo.

THE third Pedler lecture before the Chemical Society, entitled "The Life and Work of Otto Wallach", will be delivered by Prof L. Ruzicka, of Zurich, on March 10, at 5.30 P.M. The lecture will be given in the Meeting Hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W.1. Tickets of admission will not be required.

At the annual general meeting of the Association of Economic Biologists held on Feb 26, the following officers were elected: *President*, Dr W. B. Brierley, *Vice-Presidents*, Dr W. R. Thompson and Mr A. D. Cotton, *Hon. Treasurer*, Dr J. Henderson Smith, *Hon. Editors*, Dr W. B. Brierley and Mr D. Ward Cutler, *Hon. Secretaries*, Prof J. W. Munro and Prof W. Brown.

WE have already referred to the sixteenth Annual of the Paris Academy of Sciences (Feb 6, p 199), which contains a complete list of members, going back to 1795. The Academy has now issued a small volume containing a list of members and *correspondants* during the period 1666–1793 (Paris: Au Palais de l'Institut, 23, quai de Conti, 1931). This list was compiled by M. A. Lacroix, and gives the dates of birth and death, biographical notes, and posts held by the members.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned—An assistant biochemist at the General Hospital, Birmingham—The House Governor, General Hospital, Birmingham (March 12). An aircraft and engine inspector under the Government of India—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (March 12). A principal of the Sheffield City Training College for Teachers—The Director of Education, Education Office, Sheffield (March 14). An assistant medical secretary of the British Medical Association—The Medical Secretary, British Medical Association, Tavistock Square, W.C.1 (March 14). A professor of education and head of the men's training department of the University College of South Wales and Monmouthshire—The Registrar, University College of South Wales, Cardiff (March 22). A professor of geology in the University of Birmingham—The Secretary, University, Birmingham (April 11). A woman lecturer in biology at Edge Hill Training College, Liverpool—The Principal, Edge Hill Training College, Liverpool (April 19). An assistant bacteriologist in the Central Tuberculosis Laboratory of the King Edward VII Welsh National Memorial Association—The Bacteriologist, Institute of Preventive Medicine, The Parade, Cardiff.

### Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### Metastable Atoms in Mercury Fluorescence

MERCURY vapour of low pressure stimulated by the resonance line  $\lambda 2537$  emits fluorescent light for a time of the order of  $10^{-3}$  sec. This allows the fluorescence, when generated in a moving current of vapour, to travel away from its place of origin. The fluorescent light shows a spectrum of continuous bands. No complete or satisfactory account of this phenomenon has yet been given, and I do not think that the facts so far available are enough to make it possible.

It has been suggested by Franck and others that metastable mercury atoms or molecules are involved. I do not here enter upon any speculative considerations, but wish to give a short preliminary account of some experiments which prove that both kinds of metastable mercury atoms are in fact present in the stream of fluorescent vapour, when it is excited in the first instance by the resonance line.

Metastable atoms are not readily brought into evidence directly, but they can be tested for by

Fig 1

applying further excitation and observing the result. The lower kind of metastable atom,  $2^3P_0$ , requires the higher frequency (violet) to bring it to  $2^3S_1$ , the higher kind,  $2^3P_2$ , is raised to the same level by green radiation. The achievement of the level  $2^3S_1$  is brought into evidence by the complete visual triplet being emitted, and we can look for whichever component of the triplet is most convenient.

Fig 1 will help to explain the method of applying the test. The exciting resonance radiation comes in from the left through a small aperture in a metal diaphragm. The green fluorescence is seen to spring from the place where it enters the vapour, streaming up with the vapour as indicated. This fluorescence by no means distributes itself over the whole cross section (2 cm square) but remains isolated, with comparatively slight lateral spreading. At a distance of, say, 1 cm up, it meets with the converging beam of violet light,  $\lambda 4046$ , coming from the right, and where the violet beam traverses it, a marked increase of luminosity is observed. This consists mainly of the green line  $\lambda 5461$ , and indicates the presence of  $2^3P_0$  atoms, which are raised to  $2^3S_1$  by absorption of the violet line, and then (no doubt) emit the complete visual triplet. The green component is the best to observe, because there is no false light of this wave-length present. Moreover, it has the

advantage of being favourable for visual observation. The beam of violet light can be swept up and down, and the local development of the green mercury line can be watched, following closely the contour of the initial green fluorescence which has a continuous spectrum.

A similar experiment proves the presence of  $2^3P_2$  atoms, but in much smaller numbers. In this case the auxiliary illumination from the right consists of the green line  $\lambda 5461$ , which is absorbed by  $2^3P_2$  atoms and raises them to the  $2^3S_1$  level. The visual triplet is generated as before. The glare of green light already present makes it impracticable to observe the secondary development of this line, and the observation was made photographically by means of the blue and violet lines.

The same method is applicable to determine the distribution of  $2^3P_1$  atoms, but is not nearly so convenient for this purpose as the direct photography of resonance radiation. I do not enter into this matter here, beyond remarking that the  $2^3P_1$  atoms do not follow the distribution of the green fluorescence, their distribution being altogether different.

#### Light as a Factor in Sexual Periodicity

IN the discussion which followed the papers by Dr J R Baker and Mr R M Ranson and Prof T H Bissonette, read before the Royal Society on Feb 4, I suggested that their conclusions concerning light as a factor in sexual periodicity involved a principle of wide application. Dr Baker had referred in his paper to the practical application of this principle by the poultry industry, and I remarked that Mr Hammond had pointed out to me that it was possible to construct graphs for the principal countries of the world showing a well-marked correlation throughout the year between egg production and the incidence of daylight. I stated further that the effects of artificial illumination were known also to breeders of canaries and other cage-birds, and that within my own experience the collared turtle-dove which has been kept under conditions of domestication for many generations will breed freely under ordinary room conditions in mid-winter under the added stimulus of artificial light in the evenings. I might have added that in tropical countries where environmental conditions are similar throughout the year, such as the Cameroons, the native birds have no restricted breeding season but breed at any time. Moreover, in the case of the Brent goose and various other species of geese, although pinioned birds may be kept for years in a state of perfect health in semi-captivity, they never or very rarely breed, and I suggested that such birds require the stimulus of prolonged daylight, which they obtain in their normal breeding habitat within the arctic circle, in order to excite the activity of the reproductive organs.

In the discussion, criticism was afterwards made as to the general application of the principle, and it was remarked that nocturnal animals, such as the bat, and animals that live underground, such as the mole, breed at certain seasons without the stimulus of daylight. Owing to lack of time, the discussion closed and it was not possible to reply to this criticism, otherwise I might have pointed out that the bat in its reproductive processes is a peculiar animal, at least in the case of the common pipistrelle and some other British species, since normally they copulate in the autumn and do not ovulate until the spring. ### A Programme for Human Genetics

*Genetic Principles in Medicine and Social Science*

By Prof Lancelot Hogben Pp 230 (London  
Williams and Norgate, Ltd, 1931) 15s net

WHEN the history of genetics comes to be written, the beginnings of human genetics will not form its most creditable chapter. Theory outran practice in its development. The biometricians used the coefficient of correlation as a universal tool, the Mendelians attempted to force the data into the even more Procrustean frame of 1:1 and 3:1 ratios, the eugenists proposed the solution of very complex social problems on the basis of quite inadequate data. Meanwhile, opponents of the genetical point of view asserted that innate factors are of no serious importance in determining human conduct. Human genetics to-day are still in this highly uncritical stage of development, but Prof Hogben's book is at least the herald of a more scientific epoch.

The book is mainly occupied with criticism of former work in the same field. The first chapter deals with the relative importance of nature and nurture as revealed by the study of monozygotic twins and of adopted children. Its results will disappoint fanatical believers in the omnipotence either of heredity or environment. But at least they show that the problem can be solved, and that any solution must be quantitative. For any given character showing variation in a given population, it should ultimately be possible, by Fisher's method for the analysis of variance, to estimate the fractions of the total variance due to differences of environment, differences of ancestry, and segregation, respectively. The results will differ widely, not only for different characters, but also for the same character in different communities. Thus, at present adult illiteracy is mainly determined by nature in England, nurture in India. But a vast amount of further work is required before quantitative results are possible.

Geneticists will find the next three chapters most interesting. Prof Hogben gives a critical analysis of

the evidence that some human characters, such as albinism and colour-blindness, are inherited according to Mendel's laws. While the figures for colour-blindness agree perfectly with theory, those for albinism deviate by 4.7 times the standard error. This is not, of course, surprising, seeing that several distinct combinations of genes will yield a pink-eyed white rabbit, but it shows the danger of assuming determination by a single gene without critical and quantitative testing of the data. Unfortunately, it is doubtful whether Prof Hogben's method of analysis is the best possible. It is, at least, a vast improvement on none at all. The inheritance of the blood group genes and Bernstein's beautiful and powerful method for investigating linkage are next described. Then follows a discussion of the genetical basis of mental defect. It emerges that while, for example, amaurotic family idiocy is a simple and recessive character, Mongolian idiocy is mainly determined by an unknown environmental factor, and feeble-mindedness, an extremely ill-defined condition, depends both on nature and nurture, even if the former is the more important. Among the most interesting characters considered is the possession of blue sclerotics, generally with fragile bones. It appears that this condition can be caused either by a dominant gene or by prenatal environment in a mother carrying this gene. Frost found that seed colour in *Matthiola* is determined in exactly the same way.

A chapter on race, which demonstrates the lack of evidence concerning innate psychological differences between races, is followed by a discussion of selection. As this is largely a résumé of my own work, I should like to emphasise that it was Punnett in 1917 who first calculated the extremely slow rate at which rare recessive characters would disappear from a population were their bearers prevented from breeding. It is pointed out that the effect of eugenic measures would depend on the mode of inheritance of the characters encouraged or discouraged, and that cousin marriage may be a fruitful source of human abnormalities. Thus, in a group of mental defectives here cited, only

5 per cent had defective parents, whilst in a group of insane, 8 per cent were the offspring of marriages between first cousins. If these figures are representative, a revival of the prohibition of cousin marriage might be a more eugenic measure than the sterilisation of the feeble-minded.

In the last two chapters, Prof. Hogben gives his views on the social application of eugenic principles. He is careful to point out that such views are inevitably biased by the writer's political and other opinions. He succeeds, however, in demonstrating that there is no necessary connexion between the study of eugenics and the ultra-conservative opinions so often associated with it.

The book does not attempt to cover the whole field either of human genetics or of eugenic proposals. It contains one or two very dubious statements, for example "The genetic constitution of an individual depends on the identity of the parents. It does not depend on whether he or she happens to be the first or fifth child of a family." This neglects the fact that both linkage and selective elimination may vary with age. Nevertheless, no serious student either of genetics or eugenics can possibly afford not to read the book. If it provokes an answer on the same scientific level from a holder of what may be called the orthodox eugenic view, it will have done an immense service to the eugenic movement. Until such an answer is forthcoming, the present unfortunate breach between genetic research and eugenic propaganda is likely to be widened. An adequate answer to certain of Prof. Hogben's criticisms would serve to heal this breach. It is doubtful if anything less will do so.

J. B. S. HALDANE

### Psychology with an Anthropological Background

*The Psychology of a Primitive People: a Study of the Australian Aborigine.* By Prof. Stanley D. Porteus. Pp. xvi+438+48 plates. (London: Edward Arnold and Co., 1931.) 30s. net.

IN these days of specialisation, when a specialist has been defined as a person who knows something about his own subject and nothing about any other, a book such as this, which successfully combines two methods of approach to the problem in hand, is of exceptional interest and importance. Its author, primarily a psychologist, is also an experienced field anthropologist, who knows how to make friends with primitive folk, and how to take full advantage of opportunities for personal contact with them in their natural surroundings. Con-

sequently, he realises the importance of certain aspects of the problem he has set himself which are too often overlooked by writers on racial intelligence. As one out of many instances may be cited, the emphasis here laid on recognition of the fact that intelligence is manifested not only by capacity to meet new situations (which is, on the whole, the quality brought out by mental tests) but also by the ability "to deal with the age-long problems of the race, the struggle for survival and the reconciliation of man's individual and social needs."

The first portion of the book is accordingly devoted to a description of the country and the natives "under the guise of a narrative of the expeditions", so vividly written that it must surely put before the unaccustomed reader a picture scarcely less clear than the memories it will call up to those who are familiar with country of the kind described. "As far as we could see there was no living thing visible, it was as though Life had taken one look at the place and gone away. Yet somewhere out on those wastes are groups of natives maintaining a precarious existence, ceaselessly hunting for food day after day from dawn to dark." Against this background the author makes his natives live and move before us, and then—but not until then—he proceeds to analyse their behaviour, and to show how "at every point this behaviour is attuned to the hard conditions of their lives." He acknowledges, as must everyone who writes on Australian aborigines, his debt to Spencer and Gillen, but his account is full of first-hand experiences, since he gained the confidence of the natives so far as to be admitted to their ceremonies and shown their most secret treasures.

Social anthropologists will be interested in the chapters giving an analysis of native customs and institutions from the point of view of a psychologist. In discussing the characteristic features of Australian native society, such as their initiation rites, their marriage regulations, and the position accorded to their old men, the author develops his view that these and other observances have as their purpose "to knit the bonds of social cohesion closer, and to provide a counterbalance against socially disintegrating tendencies."

The third section of the book deals with mental tests and physical measurements, to which are added some interesting comparative data. The author does not assume too much knowledge on the part of his readers, but gives full descriptions of both tests and measurements, in terms intelligible to the non-specialist. In view of the unfortunate absence of uniformity which prevails

among physical anthropologists, he might well have gone a step further and stated exactly what technique was used, particularly in the case of sitting height and head length. He gives a detailed statement of the present position in regard to the vexed question of the relation between head size and intelligence, a subject to which he has devoted much attention in earlier studies of mental defectives and others.

In regard to the mental tests, Prof. Porteus is very clearly aware of the exceptional difficulties encountered when these are applied to people of primitive culture, and is correspondingly cautious in his interpretation of the results obtained. Of special interest is the attempt to devise tests in harmony with the cultural background of the natives, with the view of examining "the capacities fundamental to some aboriginal aptitude or skill." Thus their well-known ability as trackers suggested a test consisting in matching a series of photographic reproductions of footprints. The disadvantage of such specially designed tests lies in the difficulty of adequate standardisation, to ensure that the results of tests devised to suit different cultural conditions may be usefully interpreted and reasonably comparable. But apart from this, there would appear to be a definite place for such tests, if they really differentiate between degrees of capacity within a group. Many teachers of American Indian children in government schools have told me how thankful they would be for a test which would help in grading new-comers from the reservations, since much time and labour is wasted before the most suitable treatment for these children is discovered in the course of the ordinary school routine.

Special mention must be made of the photographs, which are noteworthy both for their intrinsic interest and for their technical excellence.

Some minor criticisms of format suggest themselves. The concluding summary might with advantage be given due prominence, instead of being tucked away in a single paragraph at the bottom of a page which has a sectional heading. The references, given as footnotes, would be more useful if listed together at the end of the volume.

This book should be included in the kit of everyone who sallies forth to study primitive people, no matter what his transport difficulties may be. That is the highest praise a field worker can bestow. The stay-at-home student will find it equally stimulating, and, indeed, it will appeal to anyone, whether student or not, who enjoys an account of real adventure.

BEATRICE BLACKWOOD.

### Scottish Prehistory

*Skara Brae a Pictish Village in Orkney* By Prof. V. Gordon Childe. With Chapters by Prof. T. H. Bryce and Prof. D. M. S. Watson. Pp. xiii + 208 + 63 plates. (London: Kegan Paul and Co., Ltd., 1931.) 31s. 6d. net.

NORTH Scottish prehistory has not perhaps always received much attention at the hands of non-Scottish prehistorians. This has been largely due to the geographical position of the country, which has been assumed to have been rather at the end of the world, at least until the arrival of the Scandinavian sea-rovers in historical times. It is probable, however, that the north of Scotland was by no means thus always 'the back of beyond', and in this area, as well as in the nearby islands, there lived folk whose culture, though simple, was both interesting to the student and not entirely autochthonous in growth. The present book deals with a series of explorations and excavations made under the supervision of Prof. V. G. Childe in the prehistoric village of Skara Brae, in Orkney, which was in process of being conserved by H.M. Office of Works at the time.

The importance of Skara Brae lies in the fact that the village was engulfed by a sand dune, and thus everything up to a height of some eight or nine feet has been preserved. Further, since wood always seems to have been rare in those parts, the villagers had to use stone where wood, if available, would doubtless have served throughout, and thus much that normally would have perished has been preserved. Culturally speaking, the whole can only be described as Neolithic, but actually in time the period of occupation was far less remote in all probability, and was contemporary with Bronze Age cultures, or even perhaps with the Iron Age elsewhere. The folk themselves were breeders of sheep and cattle. But everything cannot be dated to one age. Indeed, no less than four periods can be determined. Around and sometimes over certain of the buildings there has accumulated midden material which is itself also divisible into layers of different ages, and it has been found possible in some cases to assign these various midden deposits to one or other of the four periods just mentioned. Further, the earliest midden actually antedates the construction of the huts themselves, though a hearth typical of later times occurs in it. Culturally speaking, there is little change throughout the whole duration of the occupation.

Causes of several abandonments of the village may well have been the steady encroachment of the sand, with which the occupants seem to have been unable to cope. The final abandonment at the end of the fourth period may have been due to violent gales which produced rapid sand incursions. Afterwards, except for spasmodic returns and casual visitors, one of whom was a viking whose tomb has been found in the upper layers, Skara Brae remained unoccupied until the time of its recent excavation.

It is difficult to give an actual date for the habitation of the village, owing to the isolated life lived by these primitive island folk. Metal has not been found, but pottery techniques recall those of the later Bronze Age. Then, again, knobbed balls occur, and these have been considered by many archaeologists to belong to the Iron Age. Prof. Childe himself has shown that their general distribution is similar to that of the Scottish Pictish symbols. Again, brochs occur in Orkney, yet Skara Brae seems to have been uninfluenced by their intrusive culture. Are we to consider that this village is post-broch, in spite of many of the objects found? Or can we consider that it is of older origin, influenced by, if not truly belonging to, the Scottish Bronze Age, but untouched by the broch-building invaders who dominated the country for a time, only to disappear later, leaving the Skara Brae folk to continue as their forefathers had always lived?

These are but a few of the many things described and problems discussed in this fascinating book by Prof. Childe. While Skara Brae cannot be said to have played a vital part in the building of European civilisation, it does present an exceedingly interesting problem of study for the prehistorian. At the end of the book there are two chapters by Prof. T. H. Bryce and Prof. D. M. S. Watson, on the skeletal finds and the animal remains respectively. In the case of the former, the result of an exhaustive examination seems to show that the population of Skara Brae belonged to the same sort of mixed types as might inhabit the place to-day. The animal bones present no special difficulties. They include the sort of food fauna we should expect to find in a village of domestic animal breeders.

Prof. Childe is to be congratulated both on his work in the field and on his book. It may further be added that the illustrations, which include a coloured plan, are exceptionally fine and numerous.

M. C. BURKITT

### A Classic of Farming

*Thomas Tusser 1557 Floruit his Good Points of Husbandry* Collated and edited by Dorothy Hartley. Pp. 195 (London: Country Life, Ltd., 1931) 21s. net.

TUSSEER'S book was written in the middle of the sixteenth century and ran through many editions, mostly in the nature of enlargements. The first, 1557, consists of a "hundreth good pointes of husbandrie." To this in 1571 were added a "Beleef" (creed), "a hundrethe good pointes of Huswifry, and divers proper lessens for housholders." In the 1573 edition, the hundred good "pointes of husbandrie and huswifry" had each become five hundred, and lessons on gardening, "hopps and other needeful matters", with an abstract before every month, were subjoined. Here first appeared the autobiography of Tusser—in verse. The last edition issued in the author's lifetime was that of 1580, but from time to time reprints have appeared.

The autobiography is full of grim humour. The woes of a chorister are set forth, followed by those of a reluctant scholar at Eton—"fifty-three stripes at once I had, for fault but small or none at all." Thence Tusser went to Trinity College, Cambridge, and afterwards to Court. After this he engaged in farming in various places, Cattewade in Essex, Suffolk, Norwich, and elsewhere. He lived for a time in London, whence he fled during the plague, and returned to Cambridge.

Although his book abounds in good advice, and its worth is attested by its popularity, poor Tusser died in a debtor's ward, bequeathing the money owed to him as his only wealth.

The book, as enlarged in the later editions, is a sort of 'enquire within upon everything' concerning a farmer's life. In addition to the purely farming matters, Tusser writes of herbs, family doctoring, the upbringing of children, the use of tools, and of many country themes.

The editor's foreword says truly: "If there be earth magic through a quill, it is here, for between the uncouth lines we hear the year pass." This for the general reader, for the country man there is much beside—the sixteenth century life and management of a small farm, the old recipes, the economies no longer practised. The rotation of crops was already known, and Tusser advises fallow-barley-peas-wheat-fallow. Grain should always be followed by a pea crop, which, failing a good sale, would fatten swine. Rye was a regular crop and ingredient of bread, and brank (buck-

wheat) was grown both for feeding stock and as manure for the land

Even the 'weeds' had their uses. Mare's-tail was gathered for polishing purposes and used by fletchers and combe-makers. Whin was put up for fencing against sheep, and broom-water used as a remedy for scab. Mast was gathered and stored for the swine. Wormwood was laid on the floors of houses as a preventive of fleas.

On the veterinary side there are interesting notes. Thus we read that horses must be bled at Christmas time, and that a bullock off his feed can be cured by slicing his tail and rubbing in soot and garlic, even to-day this legendary cure is practised. Surely too we have a 'vitamin' treatment in the giving of verjuice, made from crab apples, to the cows, a pint at a time between Christmas and May.

We get a very clear picture of the communal life of a farm, where work was hard, but was broken by feasts and holidays, each with the appropriate good fare shared by master and man, mistress and maid.

Forget not the feasts that belong to the plough

For comfort with labour should sometime be had. Such feasts are here set forth. On the other hand, we have Tusser's warnings against unprofitable servants.

Trust never to boyes, if thou trust well to spede  
Kepe never such servants as doth thee no good  
No breakfast of custome provide for to save  
But only to such as deserveth to have  
Children were better unborne than untaught  
Good servants hope justly some friendship to fele

Miss Hartley has added, in the form of footnotes, recipes and notes from contemporary sources, and the book is set with illustrations, English and Flemish, of approximately Tusser's date. A book to be savoured slowly, not taken at a gulp, but truly good fare. E G

" . . . and brought forth fruit . . . an hundredfold "

*Ministry of Agriculture and Fisheries Bulletin*  
*No 28 Artificial Fertilizers in Modern Agriculture*  
By Sir E J Russell Pp viii + 202  
(London H M Stationery Office, 1931) 3s net

ARTIFICIAL fertilisers and the breeding of new varieties of plants constitute the two really spectacular achievements of scientific agriculture, for by augmenting production they have

contributed materially to human welfare. "Too materially," says the sceptic, "we have far more wheat, barley, sugar, etc., than we can consume." Such a view, however, ignores the fact that about two-thirds of mankind, residing in the Far East and Russia, 'enjoy' a very low standard of living compared with that of most western peoples, and that China alone is said to lose several millions of population every year from starvation, direct or indirect. From the world point of view, Malthus has been right: population has tended to outstrip food supplies, but whether this tendency will persist depends upon many factors—for example, how the use of fertilisers, improved organisation of resources, transport, and distribution will affect supply, and how movements of population, the practice of birth-control, and pursuit of a high material standard of living will influence demand.

Although the consumption of fertilisers has made great strides recently, really high consumption is confined to a very few countries, and the scope for further increase is very great. Apart from financial stringency, the chief obstacle appears to be lack of knowledge, and no better book for combating this ignorance can be imagined than this recent contribution from the pen of Sir John Russell, assisted by his able staff at Rothamsted. The book—somewhat ungenerously termed a 'bulletin'—may not be a farmer's book, but it should be indispensable to agricultural teachers and advisers, as well as to the man who farms scientifically. It is a model of sound, impartial, and lucid workmanship, and the perusal of it leaves us asking for more.

The bulk of the book is devoted to descriptions of the chief nitrogenous, phosphatic, and potassic fertilisers, their effects on the growth and composition of crops, how these effects vary on different soils, and how they are influenced by the weather. History is not neglected, practical considerations like amounts, times, and rates of application of fertilisers are adequately treated, and there is a short chapter on the new concentrated complete fertilisers. Results obtained at Rothamsted occupy the centre of the stage, but there are also valuable references to work done in Germany and elsewhere. If the 'bulletin' had not been intended mainly for practical farmers in Great Britain, the author might have gone even farther afield and told us of the 'epic of superphosphate' in Australasia and South Africa, of the virtues of potash, 'super', and sodium nitrate in the great cotton-belt of America, and of the surpassing value of ammonium sulphate

for crops like sugar-cane, paddy rice, oranges, and tea in the tropics and sub-tropics, but perhaps he has these things in reserve for a future occasion

Not the least interesting feature of the book is the statistical and economic information supplied, for example, that relating to the average crop increases that are obtainable over a series of years from the use of ammonium sulphate. Basic figures of this kind are badly needed for many countries, for when supplemented by cost figures and by prices which farmers receive for their produce at the farm, they give us the essential data required to answer the question 'How much fertiliser does it pay me to put on?' The evidence given in this book certainly indicates that in normal times the use of fertilisers for nearly all crops is extremely profitable, at any rate in countries which lie within the ambit of the world's trade, but more light is required on possibilities in territories like parts of China, Siberia, and India, which, owing to deficient transport, depreciated exchange, or other causes, are cut off from the great world markets

It seems, however, impossible to set a limit to the appetite of the hungry earth for fertilisers, both natural and artificial. What would Lawes have thought had he lived to learn that the world was consuming some fifteen million tons of super-phosphate per annum only eighty-seven years after he had started its manufacture at Deptford? And how would Crookes have reacted to the news that thirty-two years after his famous utterance at Bristol the world was using more than eleven million tons a year of nitrogenous fertilisers, more than one-half of which was derived from atmospheric nitrogen? Much has indeed been done, but more remains to be done

### The Thames Estuary

*The Geography of London River* By Prof L. Rodwell Jones Pp x + 184 + 4 plates (London Methuen and Co., Ltd., 1931) 21s net

THERE are rivers mightier and nobler than the Thames broad and stately floods, masses of moving waters, which impress the onlooker with a sense of immense and overwhelming power. Even within the narrow limits of the British Isles, the Thames has no priority of length and size. But there are few waterways anywhere in the world which rival it in historical interest and significance, or in the wide range of its commercial activities. The Thames is as much a part of the fabric of English history as is the great city

on its banks, for which it is the main avenue of communication with the outer world and the chief means of transport for its trade. It is impossible to imagine London without the Thames, or to picture what the English capital would have become if it had continued to be identified with Winchester or York. To the Londoner, the Thames is a source of local patriotic pride. It is his heritage, his especial possession. "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel?" So Prof Rodwell Jones, with every justification, adopts the unofficial designation of the mariner and calls it the "London River."

Undoubtedly, there is scope for such a work as this. The City and Port of London have both been the subject of exhaustive and authoritative treatises. The River rightly claims a share of notice. To be really representative, the notice should embrace the stream from its remote source in the Cotswolds to its mouth. Prof Rodwell Jones, however, does not attempt a task of such magnitude. He is content to undertake a portion of it. His book is "about the Thames Estuary, its physical conditions and economical activities", and he deals more particularly with these matters within the limits of the nineteenth century and the first thirty years of the twentieth, contrasting the port in its physical and commercial aspects as it was a hundred and thirty years ago and as it is to-day.

By way of introduction, there is a description of the general physical setting, with a concise geological survey showing that the Thames is characterised by a duality of basins—a 'catchment basin' at its source among rocks of Jurassic age, and a 'structural basin' which is entered through Goring Gap and is constituted by the synclinalum between the Chilterns and the North Downs, containing Tertiary and Quaternary deposits. After that comes a short description of the primitive site and a discussion of the early settlements along the banks, with a consideration of the circumstances which favoured their origin and growth, grouped under such types as the bridge-port, the estuarine bluff, and the ford.

This is followed by an account of the river, as developed by natural causes and artificial measures and exploited for navigation and commerce at the beginning of the last century, this period being taken as a convenient starting-point for the main theme of the book. The physical features of the date are based on Bullock's chart of 1830, compared with one or two earlier but less reliable

and sectional publications Prof Rodwell Jones summarises the position as follows

"At the opening of the century there were no considerable docks, save only that of Mr Perry at Blackwall, and the Howland Wet Dock on the Surrey side of Limehouse Reach. On the North shore, continuous settlement had proceeded eastwards only as far as Shadwell, except that along a road used by traffic for the East India Company's store at Blackwall. On the south side, continuous settlement reached only as far as Rotherhithe. The pools were lined with wharves on both sides and various stairs led down to the shipping and to ferry-ways. There was very considerable shipping at Blackwall, Deptford, Woolwich, Erith, and Northfleet. The marshlands and marsh shores were almost free of buildings. The western embanked shore of the Isle of Dogs was the site of numerous windmills."

As regards trade, circumstances tended to concentrate shipping in or near the Pools, which were becoming congested. The Report of the Commission of 1796 furnishes statistics which show that the total tonnage of vessels engaged in the foreign trade, which entered and left the port at that date, was just over a million (1,051,508), while the coast-wise tonnage was fully a million and a half (1,662,700). The latest figures of tonnage in the book are those of 1929, but since those of 1930 are higher, we may not unjustifiably contrast the two million and a half tons of 1795 with the fifty-eight millions of 1930. It is only right to add that the returns for 1931 are showing a falling-off, due, to some extent, to the prevailing economic depression. Here it may be remarked that a comparison of Prof Rodwell Jones's figures for 1929 with the figures for the same year as recorded in the Annual Report of the Port of London Authority, suggest that, in the former, either coast-wise tonnage is not included or that some other exclusion is made. The tonnage figures for 1929 in Table I (page 132) aggregate only 40.55 millions.

So considerable a mass of material in the book cannot be discussed in detail, but it is desirable to mention two matters of outstanding interest—the tides and the river walls, or embankments. The two are interdependent, since the walls were constructed on account of the tides. As is well known, both sides of the river from London to the sea are bordered by earthwork embankments of appreciable height, which serve to protect the low-lying marshlands (covering an area of more than forty square miles) from inundation. These river walls, as they are termed, aggregating a hundred miles or more in length, contain an enormous mass of material, both clay and stone, the deposit and

facing of which must have occasioned a tremendous outlay in the first instance. The origin of the work is lost in obscurity—the walls, or the main parts of them, date back, at least, to the twelfth century, but whether they were constructed by the Normans or by the Saxons or even, more remotely, by the Romans is open to conjecture. Whatever the date and nature of their origin, they play an essential part in confining and defining the bed of the river, and in providing an extensive area of reclaimed land for agriculture and building purposes below the high-water level of many tides.

The tides of the river Thames, though not of the same order as those of the Bristol Channel or even of the Mersey, are, nevertheless, considerable. In general terms, the range of spring tides is about twenty feet, but between the level of the lowest recorded low-water and that of the highest high-water there is a difference of so much as forty-one feet. Exceptional tides have taxed the resistance of the river walls to the utmost, as was recently exemplified in the disastrous experience of Jan 7–8, 1928, when, under the influence of a surge, or disturbance, in the North Sea, due to meteorological causes, immediately following a period of heavy rainfall on a frozen surface in the Thames Valley, which produced an abnormal discharge of upland waters, the spring tide rose to exceptional heights in the estuary, topping the river walls in places and causing numerous breaches of greater or less extent, and, unfortunately, causing loss of life in the Westminster and Hammersmith districts.

The able discussion of these and other matters in Prof Rodwell Jones's book makes it one of considerable interest to the geographer, the meteorologist, the historian, the engineer, the economist, and, in fact, all those whose studies are in any way connected with the estuary of the Thames. The book is well printed in bold type and the diagrams are clearly drawn. One or two slips of the pen should be noted. Dart on p 9 should be Darent (the mistake is repeated in the index), Mr (now Sir F) Palmer's Christian name is Frederick, not Frank (p 98). On p 169, the "Daily Telegraph Mills" should be the "Dartford Paper Mills", the connexion with the London journal having ceased. Also, there is another important paper mill at Dartford and one at Greenhithe not shown on the diagram, Fig 43, on p 168. The depth of the sill at the entrance to the Royal Victoria Dock is now 20 ft 6 in, not 28 ft as given in Fig 37 (p 150). The entrance has been altered and converted into a barge entrance. BRYSSON CUNNINGHAM

### Geology of Malaya

*The Geology of Malaya* By J B Scrivenor Published with the Authority of the Federated Malay States Government Pp xx+217 (London Macmillan and Co, Ltd, 1931) 16s net

READERS of Mr Scrivenor's book on "The Geology of Malayan Ore-Deposits" will welcome this companion volume on the geology of the fascinating and enigmatic land which has claimed the author's attention since 1903. In the introduction, an interesting and instructive account is given of the history of geological investigations in Malaya, including a brief account of the Kinta tin-field controversy. It is justly pointed out that the Kinta valley does not provide a key to the geology of the country, and that while debate has been focused on that small and intricate area, the Survey Department has been occupied with the whole of Malaya. Progress has now reached the stage where linking up with the Netherlands Indies, Indo-China, and Lower Burma has become practicable. In all these lands closely accordant results have been achieved.

After a general statement of the leading geological and geographical features of the Peninsula, there are chapters dealing with the late Palaeozoic and Triassic sediments and the associated Pahang Volcanic Series. During this long period, the site of Malaya was a sea of moderate depth which was finally silted up by sediment from the east. Great crustal movements occurred later and led to great intrusions of granite, which are responsible for the valuable tin deposits of the country.

An important chapter is devoted to the granite and the associated igneous rocks. A post-Triassic age now appears to be well established, and although there are no Cretaceous sediments in Malaya, the evidence from adjoining countries suggests that the intrusions may be of late Cretaceous age. The post-granitic rocks include Tertiary coal measures, high-level alluvium which appears to be Pleistocene or older, and recent alluvium and pumiceous ash.

The remaining chapters deal successively with weathering and laterite, metamorphism, with special reference to a puzzling series of tourmaline-corundum rocks, thought provisionally to be altered bauxite, various minerals and tektites, and materials of economic interest other than ores. The book concludes with a bibliography complete to 1930 and a good index. A noteworthy feature is a colour-printed geological map of Malaya, on the scale of 12 miles to the inch, which is folded in a pocket at the end of the volume.

The book is written throughout in a clear and pleasant style, enlivened with flashes of humour and local colour. Mr Scrivenor is to be warmly congratulated on having made available in so acceptable a form the conclusions he has reached after more than a quarter of a century's arduous work in a tantalising land that has become notorious for the difficulty of its geological problems.

### Physics in the Making

*Recent Advances in Physics (Non-Atomic)* By Prof F H Newman Pp ix+378 (London: J and A Churchill, 1932) 15s

FRANKLY, we find the title of Prof Newman's new book a little puzzling. He sets out to deal with recent advances in non-atomic physics, and, knowing his flair for exposition, we looked forward to a readable account, with due emphasis given to the experimental side, of recent developments in what we might call macroscopic or molar physics. His account is readable enough, and interesting experimental detail bulks largely therein, but the choice of topics bears singularly small relation to the title. Wave mechanics, statistical mechanics, electromagnetic radiation, including a discussion of infra-red spectra,  $\gamma$ -rays, cosmic rays, and the scattering and diffraction of X-rays, ninety pages on modern magnetics, and, under the heading electricity, a discussion, *inter alia*, of electrolytic conduction and of super-conductivity. These be strange themes to meet in a work where we had hoped a comfortable certainty would reign supreme and electron waves would cease to surge and roar.

The balance is to some extent redressed by a chapter on sound, which includes discussions on architectural acoustics, on sound-ranging, filters, and ultra-sounds, another chapter dealing with low temperatures and their measurement, and sections treating of high pressure researches and of atmospheric electricity. Nay, with a little twisting of the terms of reference, we may even include such topics as liquid viscosity and surface tensions, certain aspects of which Prof Newman discusses in fairly full detail.

Truth to tell, it is impossible to make a division of topics which shall be strictly logical and shall avoid serious overlap. Prof Newman points out, perhaps a trifle optimistically, that "the whole trend of modern science is, as it should be, towards correlation." Nevertheless, we may make a very convenient, if rough division, into molar physics, atomic physics—where the concept of the billiard-ball atom still subserves a useful purpose—and

sub-atomic physics The difficulties and overlappings inherent in such a classification are obvious, but the section first-named will include topics which could very well replace some of the 'sub-atomic' sections of Prof Newman's book Photo-elasticity, recent developments in measurements of high precision, advances in applied physics, of which the Michell thrust block may be cited as an example, geophysical measurements, pyrometry—these are but a few of the topics which we should rejoice to see Prof Newman handling and elucidating with his wonted skill

We wish it to be clearly understood that we are suggesting substitution rather than addition The subjects which Prof Newman has discussed are so many and so diverse that some of them are necessarily treated in a cursory manner which, perhaps, makes the matter seem rather easier than it really is But we do not desire to seem ungrateful Prof Newman has collected a vast mass of information in the three hundred and seventy pages of his text, and the book should prove very useful to a hard-pressed generation of students which has neither the leisure nor the will, among the multiplication of subjects which crowd our syllabuses, to scan critically and to abstract for itself original papers of importance It should be added that for those who have time and inclination to refer to original sources, Prof Newman provides carefully selected bibliographies of the various topics discussed

ALLAN FERGUSON

### Biophysics in Muscular Action

*Adventures in Biophysics* By Prof A V Hill  
Pp ix + 162 (London Oxford University Press, 1931) 12s 6d net

THE attractive title of this book is fully justified by its contents Anyone who wished to sing with the Greek poet the praises of the inventive wit of man, σοφόν τι τὸ μηχανόεν τέχνας ὑπὲρ ἐλπίδ' ἔχων, could have no better example than some of the adventures in biophysics, of which Prof Hill here gives an account Technical skill and ingenuity in the use and construction of thermopiles made it possible to measure the rate at which a muscle liberates heat, when it is at complete rest, the basal metabolism of the living tissue This basal rate was measured with the muscle in air or oxygen, and in nitrogen free from oxygen It was about twice as great in oxygen as in nitrogen The life of a tissue may be regarded as consisting in the balancing of destructive catabolic changes by reconstructive anabolic changes heat may be sup-

posed to be liberated by both kinds of change In the absence of oxygen the anabolic changes would not appear

When the muscle becomes active as a result of stimulation, additional heat is of course produced, whether oxygen is present or not If oxygen is present, heat is produced for some time after the activity has ceased, and is a measure of the anabolic processes by which the muscle recovers from the changes attending activity, but finally the original basal rate is reached at the same level as before, the return is slow but complete In nitrogen the return is rapid but incomplete It is rapid because the slow anabolic processes involving oxidations are impossible without oxygen, the fact that it is incomplete seemed to mean that the effect of activity was to increase the instability of the living system and so lead to an increased rate of catabolic change A very interesting observation and a very plausible interpretation, only it was surprising that the rate of catabolic change should increase directly in proportion to the amount of activity

Among the tests to which the observation was put, was one in which hydrogen was used instead of nitrogen to displace the air surrounding the muscle The result was that the basal metabolic rate after activity seemed to have been increased more than it would have been in nitrogen, and the plausible, interesting explanation became impossible The phenomenon was then proved to be due to the lowering of the vapour pressure of the muscle by the activity In activity, a few large molecules break down into a larger number of smaller ones, the osmotic pressure rises and the vapour pressure falls Consequently, water from the solutions in the instrument, with which the vapour pressure of the muscle was previously in equilibrium, condenses on the muscle, and it is the heat released by this condensation that accounts for the apparent increase in metabolic rate of the resting muscle In hydrogen the effect is greater because of the more rapid diffusion of water vapour in the less dense gas

The thermopile has thus proved to be an incredibly sensitive means of recording minute differences of vapour pressure, 1 mm on the galvanometer scale corresponding to a change of vapour pressure of the order of 0.1  $\mu$  of mercury, or to an addition of less than 1 mgm of lactic acid to 100 gm of the solvent system of muscle It is possible to calculate from the known chemical changes in an active muscle that these are capable of accounting for not more than four-fifths of the observed change in vapour pressure, and Prof Hill argues from this as to the incompleteness of our knowledge of the

chemistry of muscle It is similarly possible to calculate whether all the water in muscle (or in egg white or blood or other such fluids) is free, in the sense that it is available for the exercise of osmotic pressure by substances dissolved in it, and the result obtained is that, within at any rate about five per cent, all of it is free

With this technique and the assistance of his colleagues, Prof Hill has collected many new data on the fascinating questions involved in the relation between the osmotic pressure of sea water and the body fluids of its inhabitants, or the descendants of its inhabitants, including man In man, he has found that the osmotic pressure of the blood, one of the primary physiological constants, but one which is two per cent lower in females than males, may be increased more than ten per cent by muscular exertion, and indeed probably as much as twenty per cent in an extreme case The experiments on marine animals performed at Plymouth have brought out a number of new facts of the greatest interest in extension of those described by Prof W J Dakin more than twenty years ago

The last two of the five lectures are devoted to some of the latest work on the time relations of the heat production in muscle, and the attempt to correlate these with the more recent data upon the chemistry of muscle, the influence of viscosity on muscle mechanics, etc Prof Hill's record of adventures in these subjects extends now over some twenty years, and the latest of them are as full of interest as any Blessed are they that seek, for they shall find what they were not looking for

### Progress in Physical Chemistry

- (1) *Photochemical Processes a General Discussion held by the Faraday Society, April 1931* Pp 353-573 (London The Faraday Society, 1931) 10s 6d net
- (2) *Recent Advances in Physical Chemistry* By Dr Samuel Glasstone Pp vii + 470 (London J and A Churchill, 1931) 15s

(1) **T**HE Faraday Society's general discussion on "Photochemical Processes", held at Liverpool on April 17-18, 1931, follows a similar discussion at Oxford after an interval of less than six years The interval has been marked by a rapid development of our knowledge of molecular spectra, so that it is now possible to foresee in a much more definite manner the mechanism by which the molecule is activated by the initial absorption of light In particular, it is possible by a study of absorption spectra to distinguish mere

electronic activation from a *primary dissociation*, in which the molecule is immediately shattered by the incident light, and from *predissociation*, in which the activated molecule lives long enough to execute a few vibrations and thus to give rise to a band spectrum, but not long enough to exhibit a quantised rotation, so that the absorption bands are devoid of fine structure

At the Liverpool meeting, of which a report has now been issued as a separate volume, this aspect of modern photochemistry was admirably set out by Prof Mecke, in an introductory address to the section of the discussion on molecular spectra in relation to photochemical change A similar introduction to the section on photochemical kinetics in gaseous systems was given by Prof Bodenstein This address was noteworthy for the evidence submitted that, whilst chain reactions are a frequent sequel to photochemical activation, it is extraordinarily difficult to identify the links in the chain In the photochemical combination of hydrogen and chlorine, where the largest number of data are available, no theory has yet been developed which explains all the known facts, and it may be suspected that in other cases the completeness of the explanation may be due to lack of data rather than to correctness of theory It is, however, now possible to identify certain molecular fragments, such as the hydroxyl radical, by means of their band spectra, and thus to establish their real existence as intermediate products of photochemical change, and Prof Bodenstein has himself proved the intervention of  $\text{ClO}_2$  by isolating this radical in a polymeric form as  $\text{Cl}_2\text{O}_6$

Prof Berthoud's introduction to the section on photochemical change in liquid and solid systems was concerned mainly with the mechanism of activation and deactivation, and with the problem of explaining the influence of wave-length and temperature on photochemical efficiency Finally, the introductory address to the last section of the discussion was given by Prof Baly, on photosynthesis, and described experiments made during the past three years to secure increased photochemical efficiency by the preparation of better catalysts, and in particular by freeing them from alkaline impurities

Papers on the photographic process were contributed by Prof Eggert, of Leipzig, who was present and took part in the discussion, and by Prof Weigert, of Berlin Prof Warburg, of Berlin, read a paper on the application of the law of photochemical equivalence to vital processes Dr. Franckenburger, of Ludwigshafen, also read

two papers, but Dr Herzberg, of Darmstadt, and Prof Rollefson, of Berkeley, were unable to present their papers in person. The organising committee (Profs Allmand, Baly, and Porter, Dr Griffiths and Dr Norrish), the members of which contributed six papers to the discussion, were fortunate in securing such widespread support, and have added another item to the record of successful efforts which stand to the credit of the Faraday Society as an organiser of discussions of international interest and scope.

(2) Dr Glasstone has had a straightforward and congenial task in giving an account of "Recent Advances in Physical Chemistry", since his book is addressed to senior students, who may be assumed to possess all the preliminary knowledge that is needed in order to appreciate the most recent developments of physical chemistry. On the other hand, he has not abused this advantage by wandering unnecessarily into the domain of pure physics or by using mathematical methods that are beyond the capacity of the majority of chemists.

Dr Glasstone's first chapter is a long one on the electronic theory of valency. This is developed on simple lines from a consideration of quantum numbers, without introducing a detailed theory of atomic spectra. The various types of valency are then discussed, the 'co-ordinate link' being represented by a single arrow, which the author finds it necessary to distinguish from the directional arrow of a chemical equation by printing the latter in heavier type. In this connexion, attention may be directed to the real advantages which follow from representing these mixed valencies by making use of the hypothesis of localised atomic charges, which was developed for this purpose by the reviewer in 1922, and has now been sanctioned from the point of view of wave mechanics by its systematic use in Pauling's recent paper. In the present chapter it would have eliminated a fictitious lack of symmetry from the formulæ assigned to the sulphite, sulphate, acid fluoride, borofluoride, and ammonium ions, when formulated as products of co-ordination, it would also have got rid of a similar lack of symmetry in the formulæ for the polymeric forms of the water molecule, and have prevented an obvious error in the translation into electronic nomenclature of Moore and Winnill's formula for the undissociated form of ammonium hydroxide.

The second chapter describes the applications of the parachor to valency problems, including the much-debated single electron bond, on lines that are already familiar from Sugden's own book on the "Parachor and Valency". The third and

fourth chapters are on dipole moments and molecular spectra. Useful summaries of recent work are given in each case, and these two chapters may be regarded as completing the section of the book in which the structure and properties of chemical compounds are discussed.

The central section of the book is concerned with chemical reactions, and also includes four chapters, since a chapter on homogeneous gas reactions is followed very logically by one on photochemical reactions, whilst the chapter on heterogeneous catalysis is rightly preceded by one on the properties of surfaces. The remaining three chapters are concerned with solutions, under the three headings of "Solubility", "Strong Electrolytes", and "Acid-Base Catalysis", leading up to the modern theory of acids and bases and their activity as catalysts.

It is not practicable in a brief review to refer in detail to these individual topics, but at each point at which the reviewer has sought to check up the information given, it has been found that recent advances have been correctly recorded and adequately discussed. The book can therefore be recommended without hesitation to those advanced students who may wish to supplement the information given in the more systematic books on physical chemistry by studying some of the 'live topics' which are now conspicuous in physical and chemical literature.

### Properties of Steam

*The Revised Callendar Steam Tables (1931)* Calculated by Dr Herbert Moss from the New Data and Formulæ of the late Prof H L Callendar. Published for the British Electrical and Allied Industries Research Association. Pp 56 (London: Edward Arnold and Co, 1931). With thumb index, 12s 6d, without thumb index, 10s 6d.

THE "Enlarged Callendar Steam Tables" published in 1924 gave the properties of steam up to 2000 lb per sq inch. It was known, however, that the quantities above 500 lb per sq inch would require revision when more exact experimental information became available. With the assistance of the British Electrical and Allied Industries Research Association, Prof Callendar was enabled to extend the researches by making direct measurements of the total heat of both water and steam at pressures up to 4000 lb per sq inch, and temperatures up to 750° F. The measurements covered the whole of the critical region and showed that the objection to the Joule-Thomson equation, first applied to steam by Callendar in 1900, had no

foundation in fact. A general account of the theory and equations was communicated to the Royal Society in 1928 and a set of skeleton tables, calculated from the modified equation, was included in the Report to the Research Association and reprinted in a paper presented to the Institution of Mechanical Engineers in 1929.

Dr Herbert Moss has increased the debt which engineers owe to the late Prof Callendar by his work, which has led to the present volume of tables. He has re-calculated the whole of the values at lower pressures and has extended the tables to 4000 lb per sq inch and 1000° F. The values of the saturation temperatures at the higher pressures and the corresponding values of the other properties of saturated steam differ slightly from those given in the skeleton tables of 1929. A re-determination of these saturation temperatures has been made by Mr G S Callendar and Mr A C Eger-ton, and their values appear in the present tables.

Three tables in all are given. Table I includes the properties of dry saturated steam and water at saturation temperature from 29.6 inches of mercury vacuum to 30 inches of mercury positive gauge pressure. Table II (pp 16-55) gives the properties of dry saturated and superheated steam from 1 lb to 4000 lb per sq inch. Table III shows the values of  $P^{3/13}$  for use in calculating adiabatic heat drops. Fahrenheit units are used throughout. The tables are preceded by a short account of the Callendar equations with the new constants, together with explanations of methods of interpolation. The size of page adopted, 11 inches by 8 inches, enables each table to be clearly presented and easily read. The printing is beyond reproach and the thumb index is a useful adjunct. No engineer engaged in steam engine and steam turbine design can afford to dispense with this volume.

### Stainless Steels

*Stainless Iron and Steel* By J H G Monypenny  
Second and revised edition. Pp ix + 575 + 55  
plates. (London: Chapman and Hall, Ltd.,  
1931.) 25s net.

**D**URING the five years which have elapsed since the publication of the first edition of this work, the metallurgy of the stainless steels has developed very rapidly. Much research, in which Great Britain has taken its full share, has been carried out upon their metallography and properties. As a result many new types of stainless steels with much higher contents of chromium, with or without nickel, copper, tungsten, etc., have

been developed. In order to deal with these newer materials, the present edition has been almost completely rewritten and more than doubled in size. It is a book of first-class merit, prepared by one who is perhaps the foremost authority in this particular field.

How complex this group of steels has become may be realised from the fact that no less than thirty-seven pages are required for the consideration of the principles underlying the choice of a particular steel for a specific purpose. Further, steels which started their public life less than twenty years ago merely as materials resistant to atmospheric corrosion or to chemical attack have developed, in addition, into alloys the mission of which is to resist oxidation and to retain their strength at high temperatures. Nearly sixty pages are, therefore, devoted to the discussion of the rate of oxidation and the mechanical properties of certain of these steels at temperatures up to 1000° C.

From the time at which the steel leaves the manufacturer's hands to that at which the finished article is ready to be put into service, it may pass through many processes of fabrication and much harm may be done. Much good material has been irretrievably ruined by the use of processes—of welding, for example—which have proved quite satisfactory when applied to ordinary carbon steels. The dangers which beset the fabricator, and the precautions to be adopted, are matters which demand full and specific consideration. In discussing such matters the author's wide practical experience enables him to be of very real assistance. Although certain difficulties are still incompletely overcome, the knowledge where trouble may occur is of itself a valuable asset. Even if it does no more than carry one to those to whom these steels have been made a subject of special study, much that is good will have resulted. These materials are of great complexity and their metallographic characteristics still very far from being completely elucidated, a fact which the very tentative nature of the author's attempts to deal with the effects of chromium upon the iron-carbon diagram emphasises.

That the book represents a most important addition to the metallurgical literature of the special steels no one can doubt. The first edition has been out of print for three years, but in the result the delay in presenting this second edition has been eminently justified.

There is one further incidental point which deserves mention. A very considerable amount of the new data contained in this volume has been

obtained by the author in the laboratories of the firm with which he is associated. Permission to publish this mass of information would, even a very few years ago, have been almost unthinkable. It argues well for the enlightened views of this firm that it is now possible to do this, and is a good augury for a much more rational attitude on the part of other industrial organisations to an interchange of knowledge which, in the end, will be to the good of all.

### Harmonic Analysis

*The Theory of Spherical and Ellipsoidal Harmonics*

By Prof E W Hobson Pp xi+500 (Cambridge At the University Press, 1931) 37s 6d net

THE need for a treatise on harmonic analysis, more particularly on spherical harmonics, has been recognised for a long time by mathematicians who teach the subject or who find it necessary to use spherical harmonics in their investigations. Those who had the good fortune to be introduced to the study of the subject by the author of the present work had always hoped that he would find time to undertake the preparation and publication of such a treatise. It may be said at once that the work now published fulfils the expectations they had formed. Although many books which contain information about spherical harmonics have appeared since the publication of Heine's "Kugelfunktionen", none of them has claims to be considered a complete treatise on the subject, and Heine's work, though it has proved of great service to students of the subject and to mathematicians who had occasion to use harmonic analysis in their investigations, is a compilation of results which contains the material for a treatise rather than a treatise. Much has been written on the subject since the appearance of Heine's two volumes. The mere perusal of the literature involves much labour, and the task of selecting from this mass of literature what is of prime importance to students of the subject and what is necessary for the mathematical physicist is one which demands a wide knowledge of the related branches of mathematics and of applied mathematics. That the author has fulfilled these requirements the present treatise is the evidence.

The first four chapters give a complete account of the origin of the ordinary spherical harmonics, Legendre's coefficients of the first and second kinds and the associated functions are treated in detail, their more important properties are developed, and their expression in the form of series and of definite

integrals is investigated. Solid harmonics are discussed fully, the addition theorem for ordinary spherical harmonics is established, and the connexion of the functions with potential theory is dealt with. The results given in this part of the treatise are sufficient for the solution of the problems of potential theory and of other branches of mathematical physics where the space under consideration is the space inside or outside the surface of a sphere or the space between two concentric spheres.

Spherical harmonics of general type are then discussed, the treatment follows the lines of the author's classical memoir on the subject, which was published in the *Philosophical Transactions* for 1896,\* and contains the principal results, including expressions for the functions in the form of series and of definite integrals, the further developments which have been made later are also taken account of. Asymptotic expressions for the Legendre functions are obtained, the order of the approximation in different cases is carefully discussed, and the same methods are applied to obtain the corresponding results in the case of the general harmonic functions. The representation of a function by a series of Legendre coefficients or of Laplace coefficients is fully investigated on the same lines as Fourier series have been treated in the author's treatise on functions of a real variable. The corresponding series which occur in the theory of potential when the space is not that between two concentric spheres might have been treated in much the same way. An interesting chapter is devoted to the addition theorem for general Legendre functions. The zeros of the spherical harmonics as functions of the argument and also as functions of the order are fully discussed, and this is followed by an account of the properties of the spherical harmonics which occur in the theory of potential and kindred problems in connexion with the ellipsoids of revolution, the anchor ring, the cone, and the spherical bowl. It may be noted that Mehler's functions are not the harmonics which occur naturally in problems of potential theory when the space has as part of its boundary a cone.

There is a short account of ellipsoidal harmonics which contains most of the results which are required in ordinary applications, reference to Green's work in this field in his memoir on the "Laws of Equilibrium of Fluids Analogous to the Electric Fluid" (*Camb Phil Trans*, 1833) might have been useful.

Ample references to the originals have been given.

\* "On a Type of Spherical Harmonic of Unrestricted Order and Argument"

throughout the book, and a useful index has been appended. The author is to be congratulated on his success in presenting the results of different investigators as a connected whole, and on having produced a treatise which will be the standard treatise on the subject for a long time.

### Mathematics for the Practical Man

*Mathematics for Self-Study Series* By J E Thompson (1) *Arithmetic for the Practical Man* Pp xiii + 269 (2) *Algebra for the Practical Man* Pp xviii + 291 (3) *Trigonometry for the Practical Man* Pp x + 204 (4) *The Calculus for the Practical Man* Pp x + 323 (London George Routledge and Sons, Ltd, 1931) 7s 6d net each volume  
(5) *Mathematics a Text-book for Technical Students* By Bevis Brunel Low Pp vii + 448 (London, New York and Toronto Longmans, Green and Co, Ltd, 1931) 12s 6d net

THE science of mathematics, the most fundamental of all intellectual activities, has been studied since the dawn of history, and almost certainly before that. The motives which impel this study are various, but it would scarcely be an exaggeration to say that everyone uses mathematics in one form or another. In the past, many of the advances of pure mathematics have been bound up with practical applications. For example, it is probably not often realised that the Gibbs phenomenon of Fourier series was brought into prominence by results obtained in using the harmonic analyser of Michelson and Stratton, and was at first attributed to an inaccuracy in the machine itself.

The fascinating study of pure mathematics for its own sake is an occupation which is of necessity confined to a few who have their own specialised literature available. The corresponding class of students of advanced applied mathematics are also catered for. But beyond these specialists there remain two other larger classes, those who are interested in scientific activities generally, especially such aspects as can be appreciated by a general knowledge of elementary mathematics, and those who regard mathematics as a working tool in their daily pursuits and wish to extend their knowledge for severely practical aims. To treat these as potential specialists in mathematics would be a great mistake, and it is only fair that literature should be available which will meet their needs.

The books listed above are essentially intended for the student who is interested in the meaning and simpler technique of mathematics but has no

teacher to help him. They are written in a pleasant and somewhat diffuse style so as to anticipate, so far as possible, the difficulties of those who have to follow a written explanation unaided. A paragraph from the preface of (2) deserves to be quoted, and points a moral which should not be overlooked by teachers of elementary mathematics.

"The book is rigorous in that it is scientific in its approach. It attempts to explain and not to side-step obstacles and difficult points. There can be no non-mathematical book on mathematics, and popularisation may only be gained through clarity of expression and through a human and common-sense approach with a minimum of formality."

An author who expresses this view demands respect, the more so since he has acted upon the principle here stated throughout the four books of the series.

The book on the calculus deserves special notice on account of its novel manner of approach, namely, by the method of rates and not by the method of limits. The idea of limit is of course implicit in that of rate, so that the student starts at a more advanced point than usual, but at a point which appeals to the practical mind and from which it is possible to obtain and employ the simpler results and methods without straining the reader's capability. This book has been written with amazing skill, and forms a fitting conclusion to a series which certainly fulfils the author's aim of catering for those who wish to obtain a practical mastery of some of the more usual and directly useful branches of mathematical science.

The books are well worth reading, they are eminently readable, and, in spite of the impression which might be conveyed by the titles, they do not make the main ideas subservient to practical problems. They have a wealth of fully worked examples and plenty of exercises.

(5) This book is of a rather different character from the foregoing, as it supplies a comprehensive course in analysis of a rather more advanced kind. It is intended for those who wish to make practical use of the subject in engineering, physics, chemistry, and other technical sciences. The author, however, does not call his subject "Practical Mathematics", for, as he justly points out, there is plenty of room for a difference of opinion as to what is practical. The book covers a wide range from simple equations to elementary differential equations. An excellent feature is the plentiful use of diagrams, of which there are 409. There are many well-chosen, worked examples and numerous exercises. The book can be recommended. L M MILNE-THOMSON

is just possible that the delayed ovulation in these animals is correlated with the comparative absence of the light stimulus. However, the common bat does come under the influence of daylight to a certain extent, as may be seen even in mid-winter on any mild days. Thus, in January, which was notoriously mild, I observed bats in the late afternoon flying in the light of the setting sun, and Dr Rastall observed them at mid-day. Moreover, as described by Heape in his lately published posthumous book, several species of bats are migratory and 'follow the twilight'. With regard to the mole, it is well known that these animals do spend some time above the surface of the ground. For a description of their habits in this respect, Millais's book on the "Mammals of Great Britain and Ireland" may be consulted.

It is obvious, however, that although the principle enunciated by Dr Baker and Prof Bissonette is probably of extensive application, as shown by the general tendency for animals to breed in spring, the degree of response varies greatly for different species, and in some, possibly, scarcely any light at all is necessary. Furthermore, it is evident that the recurrence of breeding must depend upon other factors, of which the natural internal rhythm is most certainly one. The black swan and the *Cereopsis* goose in captivity in England, as well as other animals referred to in my "Physiology of Reproduction", illustrate this point.

It is interesting to note that Dr A. S. Parkes had at one time contemplated the possibility of light as a factor in determining the onset of reproductive activity, for, working with Miss M. Hill, he exposed two ancestrous ferrets to ultra-violet light but found that this had no effect on the sexual processes of the animals, a negative result on which he comments.<sup>1</sup> Mr S. Zuckerman, in his recent book, in describing this experiment, remarks that light appears to be an unimportant factor in determining the onset of sexuality, but he refers to Dr Baker's results in a footnote. Had Dr. Parkes made use of rays from the other end of the spectrum, as was done by Prof Bissonette for starlings, he would probably have obtained a positive result.

Lastly, it may be remarked that if any cogency is attached to the argument derived from the bat and the mole, it applies equally against the now universally accepted view as to the physiological action of ultra-violet light.

#### Number of Free Protons in the Nucleus

WHEN one tries to establish a connexion between the nuclear spin and the number of protons (not bound in  $\alpha$ -particles) in the nucleus, one is led to examine the possibility that not as many protons as possible are combined as  $\alpha$ -particles, very suggestive in this respect is the case of bismuth (nuclear moment  $\frac{3}{2}\hbar/2\pi$ ), the nucleus of which may be assumed to be

$$A = 209 = 52\alpha + 1p + 22e \text{ or, as a first trial,} \\ A = 209 = 50\alpha + 9p + 26e$$

From a general point of view, one now would expect that in the neighbourhood of  $A = 100$  ( $A$  = atomic weight), one  $\alpha$ -particle must be assumed to be split up into protons and electrons.

This assumption has an influence on the energy of binding  $E_b$  of the nucleus, which is given by the equation

$$E_b = [n_\alpha m_\alpha + n_p m_p + n_e m_e] - A,$$

where  $n_\alpha$ ,  $n_p$ ,  $n_e$ ,  $m_\alpha$ ,  $m_p$ ,  $m_e$  are the numbers and the masses of the  $\alpha$ -particles, free protons, and free elec-

trons contained in the nucleus. In the following the term  $n_e m_e$ , as being small, will be neglected.

If one more  $\alpha$ -particle is assumed to be split up, the new value of the energy of binding will be

$$E_b' = [(n_\alpha - 1)m_\alpha + (n_p + 4)m_p] - A$$

This differs from the first expression by an amount of  $42.3 \times 10^{-6}$  ergs or about 0.030 mass-units ( $He/4$ ).

All this is well known.<sup>1</sup> It seems, however, that the above-mentioned assumption, when brought into relation with the curve of energy of binding for all

FIG 1

FIG 2

FIG 3

elements, may be of interest with respect to some difficulties one meets there. These difficulties are:

(a) The points representing xenon are very much off the curve.

(b) After xenon the curve goes up again, which means instability of all elements heavier than xenon.<sup>3</sup>

(c) Wherever in this second part of the curve a series of points has been measured, the slope of these local curves does not fit in with the general slope ( $Hg^{196}$ ,  $Hg^{200}$ ,  $Hg^{204}$ ,  $Pb^{208}$ ,  $Hg^{201}$ ,  $Bi^{209}$ ,  $Hg^{198}$ ,  $Hg^{202}$ ,  $Pb^{206}$ ,  $Hg^{199}$ ,  $Pb^{207}$ ).

(d) The points can best be represented by plotting separately the nuclei of the four different types with atomic weights  $4n$ ,  $4n+1$ ,  $4n+2$ , and  $4n+3$ . The difference between the ( $4n$ ) and the ( $4n+3$ ) curve is about 0.025 mass-unit.

These difficulties can be removed in the following way.

(a) In the case of xenon, one  $\alpha$ -particle is assumed to be split up into protons and electrons. Then the energy of binding increases  $\sim 0.030$  mass-unit and all xenon points fit the curve. (The same holds for  $\text{Mo}^{100}$ .)

(b) and (c) In the (unexplored) region between xenon and mercury the same assumption must be made again two or three times (as may be roughly estimated from the curve), so that the curve becomes smooth and goes continually downward.

(d) A highly speculative possibility is to consider the  $4n$ -nuclei of low atomic weight as ( $4n+4$ )-nuclei. Some support for this view may be provided by the general situation of the  $4n$ - and ( $4n+3$ )-curves,<sup>4</sup> and by considering the following table.

|        |                   |       |                   |       |                   |       |                  |       |                   |       |
|--------|-------------------|-------|-------------------|-------|-------------------|-------|------------------|-------|-------------------|-------|
| $4n$   | $\text{C}^{12}$   | 0.003 | $\text{O}^{16}$   | 0.009 | $\text{Ne}^{20}$  | 0.011 | $\text{Kr}^{84}$ | 0.117 | $\text{Sn}^{112}$ | 0.142 |
| $4n+3$ | $\text{F}^{19}$   | —     | $\text{P}^{31}$   | 0.032 | —                 | —     | —                | —     | $\text{Sb}^{115}$ | 0.108 |
| $4n+4$ | $\text{C}^{13}$   | 0.033 | $\text{O}^{16}$   | 0.039 | $\text{Ne}^{20}$  | 0.041 | $\text{Kr}^{84}$ | 0.147 | $\text{Sn}^{112}$ | 0.172 |
| $4n$   | $\text{Sn}^{112}$ | 0.148 | $\text{Hg}^{196}$ | 0.090 | $\text{Hg}^{204}$ | 0.094 |                  |       |                   |       |
| $4n+3$ | $\text{Sn}^{115}$ | 0.173 | $\text{Hg}^{199}$ | 0.113 | $\text{Pb}^{207}$ | 0.117 |                  |       |                   |       |
| $4n+4$ | $\text{Sn}^{116}$ | 0.178 | $\text{Hg}^{200}$ | 0.120 | $\text{Hg}^{204}$ | 0.124 |                  |       |                   |       |

(The missing values can be interpolated from the ( $4n+3$ )-curve.) If this were correct, one would have to ascribe to xenon eight (or perhaps even twelve) and to mercury as many as about twenty free protons, which would be of the same order of magnitude as the number of free electrons in the nucleus.

Some schematic diagrams may elucidate the ideas expressed under (a) to (c) as follows. Fig. 1, the ordinary diagram, must be given as Fig. 2, but ought to be interpreted finally like Fig. 3, in which more  $\alpha$ -particles are supposed to be split up.

When we return to our starting-point, the number of free protons in the bismuth nucleus, it appears to be of interest to investigate the mass defects of the rare earths, in order to make sure how many steps there are of the kind pictured in Fig. 2, in other words, how many  $\alpha$ -particles must be assumed to be split up in the bismuth nucleus.

### Leadership and the Royal Society

YOU are constantly reproving scientists for neglect of their civic duties, our crime—for most of us will plead guilty—you seem to attribute to apathy. But the cure for apathy is usually leadership, and some of us think that your reproof would be more effective if it was directed to our natural leaders. Such, for example, is the view of "H. E. A.", who, in *NATURE* of Dec. 26, calls on the Royal Society to take the lead. You do not support him, because you consider (*NATURE*, Jan. 9) that the Society is hampered by its official connexions. That may be so, but the question remains whether the Society was wise to allow its hands to be tied, your excuse does not exonerate it, unless advising the Government and administering its funds is the most important function of the Society, to which all others should be sacrificed.

Inside the Society the most various views of its functions appear to be held. I have heard prominent fellows protest that it is still, as it was originally, a club for the social intercourse of congenial intellects, and that any public interest in its doings is impertinent. But outside there is no doubt at all. There it is held that the Society exists to recognise merit by the conferment of its fellowship—a title with a financial value that few older men can afford to disdain, and a moral value that inspires genuinely many of the ablest and keenest of their juniors. Any attempt to ignore this is simply disingenuous, for the belief that the Society is an accepted aristocracy of the scientific profession determines the conduct towards it of the whole outside world, scientific and lay. It explains why the Society, subject to so much hole-and-corner criticism, is so seldom openly attacked for a critic, if a non-fellow, lays himself open to a charge of envy, if a fellow, to a charge of disloyalty to his order. And—more important for the present purpose—it explains why it is impossible for any other body to assume the mantle of leadership, while the Society refuses either to wear or to discard it.

Whether this all-important function of the Society is compatible with its relations to the Government, I leave others to determine, noting only—for my business here is merely to say openly what so many say privately—that its recent action in choosing two Government servants for its officers has been widely condemned as an unnecessary riveting of its fetters. For my main contention is that the Society had already made it impossible for itself, or for any other body, to lead the scientific profession, by far more fundamental and disastrous practices. In the article on "Exposition and Authority" in *NATURE* of Jan. 30, much of the public failure to appreciate science is attributed to our jealous individualism and our unworthily narrow conception of personal merit. There is clearly, in the article, no thought of the Royal Society in this connexion, but I maintain that it is directly responsible. It has not, of course, created these original sins of the scientific temperament, but it has committed the equally serious crime of encouraging them, and has thereby made itself one of the main obstacles to the advance of the scientific outlook in this country.

I maintain, first, that the Society, by the demands it makes on candidates for election, sets up a standard of scientific merit that is false and unworthy in precisely the manner you describe. The whole practice of requiring applicants for a public distinction to expound their qualifications might be ridiculed, and I do not suppose that the Council actually pays much attention to the application forms. But it is obvious that if any evidence of scientific merit is demanded, that evidence will come to be regarded as the basis of election. Now, the only evidence demanded is a complete list of the candidate's scientific publications. He is not asked to give a general account of his work or to distinguish between the important and the trivial, no inquiry is made concerning his knowledge or interests outside the narrow range of his specialisation, his power of influencing colleagues, pupils, and the outside world by personal intercourse or 'popular' exposition is ignored, nothing matters (it is suggested) except an imposing list of strictly technical publications. Is it surprising, then, that our journals are filled with masses of unreadable trash, that sordid disputes about priority and credit rend the scientific world, and that the world outside still regards general imbecility and narrow-mindedness as the necessary accompaniment of scientific eminence?

My second, and more serious, charge is that the Society has allowed itself to become an aristocracy without the tradition of personal service, a form of institution that has destroyed every community in which it has arisen. Election to fellowship confers rights and privileges, it imposes no duties. Of course, many fellows have done and are doing noble work for science, but in recent times no fellow has been disgraced for dereliction of duty. That can scarcely be because the Society has never admitted a black sheep to its fold, many years ago I heard two young men declare that, once they had got their F.R.S. and a comfortable job, they would do no more research, and one, at least, of them has kept his promise. Is it surprising that science lacks leaders, that we are narrowly individualistic and lack the power of combination in defence of our common interests, when we so freely give and so willingly accept coveted distinctions without demanding or offering in return the smallest exertion for the general good?

It is not for me to suggest remedies, but perhaps I may indicate what kind of body the Royal Society of my Utopia would be. It would be a body truly representative of science, because election to it would be, not the conferment of an honour, but the recognition of honour already attained. Its members would be those who were already so widely respected in their profession that the assignment of a formal title could excite no jealousy. Each member would regard it as his duty and his privilege to serve his humbler colleagues, even at the expense of his immediate interests. *Noblesse oblige* would be his motto, and any self-seeking would be a confession of unworthiness of his rank, to be visited with expulsion.

The immense influence that such a position would inevitably give would enable these leaders of science to play in the councils of the nation and of the world the part that "H.E.A." assigns to them. But such a position could only be built gradually, and even if the Royal Society mended its ways to-morrow, a generation must probably elapse before it can play the great part to which its history calls it. Meanwhile, at the risk of an anti-climax, I want to make one very minor suggestion, partly because it is immediately practicable and partly because it illustrates so well the evils of our present state.

The commercial firm by which I am employed invites all genuine seekers after knowledge to ask for such advice and information as its scientific staff can give. Its motives need not concern us, the important fact is that a surprisingly large number of persons accept the invitation, including many (such as university students) who might be expected to find help nearer at hand. It is clear that the counsel and encouragement that beginners in research (or in research in some new direction) ought to receive as a matter of course from their seniors is not always forthcoming. I suggest that here is an opportunity for the Royal Society to display immediately the spirit that is needed to reform the scientific profession. Let it be publicly declared that every fellow regards it as his duty and his privilege to give advice to colleagues on all matters in which he is expert—to give it freely, without stint, and without any idea of recompense or credit. If it would at least consider that suggestion, the Society would show at last that it is still animated by the spirit of its founders, and that it still cares as much for the welfare of science as for the dignity of its fellows.

### Cause of Twinning of Crystals

IN the course of an investigation<sup>1</sup> of optically active uniaxial crystals, I expressed the view that the possibility of twinning of a crystal was connected with a definite pseudo-symmetrical character of its structure as a whole. This statement was seriously attacked by Prof. Friedel, as may be clear from the following quotation of his paper<sup>2</sup>: "La formation de la macle est totalement indifférente à la symétrie ou à la pseudo-symétrie de l'édifice cristallin ou des groupes d'atomes qui le constituent. Elle est due uniquement à la rencontre de symétries ou de pseudo-symétries dans les *périodes* (mailles, simples ou multiples) de cet édifice."

With regard to this question, I should like to make some comments. The fact that, generally speaking, the influence of the forces exerted by atoms (ions) on the surrounding atoms (ions) does not extend over much more than their immediate neighbours, makes one inclined to believe that the fundamental cause of twinning must be looked for in the 'force-relations' in the immediate neighbourhood of the last-formed layer of the growing crystal.<sup>3</sup> These relations, which govern the addition of new atoms or ions, must be of such kind that the 'normal'—or the 'twin'—continuation of the structure represent growing-possibilities of nearly equal probability. For this reason it seems plausible to us to expect that they will show a (pseudo-) symmetrical character with regard to one or more definite directions in the crystal structure. This pseudo-symmetry, however, needs not necessarily show itself immediately in the positions of identical atoms, that is, in the pattern of the crystal structure, although there are instances where this is apparently the case, as, for example, with the twinning of aragonite<sup>4</sup>. It may also be due to a quasi-equivalence in the interatomic forces exerted by different atoms.

The undeniable experimental fact (see especially Prof. Friedel's beautiful book "Leçons de cristallographie", 1926) that in twin-crystals there is always a simple or multiple lattice unit underlying the whole twin structure is, according to my view, only another manifestation of a pseudo-symmetrical character of the structure of the untwinned crystal as a whole. To conceive it as the unique cause of twin-formation would imply the assumption, especially in the case of a twin with a relative high multiple-number of its underlying lattice, that at a certain stage in the growth of a crystal a new layer of atoms could take up the 'twin-orientation' only because, so to say, after the addition of some fourth or fifth layer, a certain number of atoms would occupy positions, which can be considered as lattice-points of a multiple lattice unit.<sup>5</sup> It leaves also unexplained, why two twin-possibilities of the same crystal, with equal multiple-number for their underlying lattice units and equal approximation of these units to exact periodicity in both parts of the twin, can show such a marked difference in occurrence that one of them is only rarely, the other frequently, observed (for example calcite, see Friedel, "Leçons de cristallographie", pp. 463-464), or why cubic crystals, which, while having identical lattice symmetry conditions, display great differences in twinning-multiplicity.

Without being able to give an explanation of these remarkable facts, I only wish to point out the necessity of assuming, besides the (pseudo-) symmetry relations of the lattices of the crystals in question, other factors playing a part in the formation of twins.<sup>6</sup> In this connexion attention may be directed to two very interesting papers, one by F. Heide (loc. cit.) and one by G. Aminoff and B. Broomé,<sup>7</sup> in which the authors arrive at the conclusion that in definite cases the faculty of twinning of a substance is apparently

connected with its faculty of being able to crystallise in more than one modification

With regard to the possibility of examining the structure of twinned crystals by means of X-rays, Prof Friedel fears<sup>8</sup> that the structure arrived at in this way will have an illusory value, in particular because it will relate to an incorrect lattice unit, namely, the lattice unit underlying the whole twin structure, which may be a multiple of the real unit cell of the untwinned crystal. While not in the least denying the presence of such a multiple unit, we deduced from our considerations<sup>9</sup> that, if indeed the X-ray investigator did find an incorrect unit cell, the danger would be greater that he would find a sub-multiple of the true cell than a multiple.

It is interesting to note that precisely this anticipation occurred in a recent X-ray investigation of crystals of the mineral boleite by B Gossner and M Arm,<sup>10</sup> who attributed to these crystals a cubic unit cell with side-length  $a = 15.40 \text{ \AA}$ . This statement was in contradiction with a crystallographic study of this mineral by Prof Friedel (dating from as early as 1906<sup>11</sup>), who from an examination of the cleavage of boleite crystals concluded that the cubic appearance is only a consequence of mimetic twinning of perpendicularly crossing biaxial quadratic lamellae with an axial ratio  $c/a$  very close to the value four. Now, from a careful X-ray investigation of a small untwinned birefringent fragment of a crystal of boleite, R Hocart<sup>12</sup> in Prof Friedel's laboratory could show that on his rotation photographs about the  $c$ -axis of the crystal some faint layer lines appeared, lying between those observed by Gossner and Arm, from which it followed that the  $c$ -axis of the unit cell of the untwinned crystal is  $62 \text{ \AA}$ , that is, practically four times as great as the  $a$ -axis. Without discussing in how far the weakness of these interadjacent layer-lines on Hocart's photographs is still an indication for the possibility of subdividing the true unit cell of boleite in four structurally closely related sub-cells,<sup>13</sup> their presence, on one hand, confirms beautifully Prof Friedel's prediction of the axial ratio of the untwinned crystal, on the other hand, it is in striking agreement with my own prediction about the danger of finding by X-rays a sub-multiple of the true unit cell instead of a multiple.

### Polarisation of Downcoming Wireless Waves

In a method which has previously been used<sup>1</sup> for determining the state of polarisation of downcoming wireless waves, the frequency of a transmitter was varied so as to produce interference maxima and minima at the receiver in the well-known way. By analysing the signal variations at the receiver, it was

possible to deduce the state of polarisation of the downcoming waves. The method suffered from two disadvantages, as follows

(1) In order to interpret the results, it was necessary to assume that the intensity and state of polarisation of the waves had remained constant during the making of the frequency change. This restricted the observations to a period just before sunrise, when the downcoming wave was found to be sufficiently constant.

(2) It was possible to carry out the experiments only in conjunction with special transmitting stations such that the requisite frequency change could be made. This restricted very much the geographical locations of the transmitting stations.

We have now developed a method of observation which gives a pictorial representation of the state of polarisation on an oscillograph screen, and can be used to analyse the wave from any transmitter emitting a steady or a modulated wave. It may also be used when the nature of the polarisation is changing rapidly, so the two objections to the original method are removed.

In the new method, the normally polarised and abnormally polarised components of the downcoming wave are received on two separate aerial systems, and, after being amplified, are applied to opposite pairs of plates of a cathode ray oscillograph. The ground wave may be eliminated by the use of suitable aerial systems. The phase relations in the receivers are adjusted correctly by employing a small local transmitter placed in such a position that it induces into both systems. The sense of rotation of an elliptically polarised downcoming wave is determined by momentarily detuning one of the amplifiers slightly.

The apparatus has been used to investigate the downcoming waves from the London National transmitter received at Cambridge during the evening hours from sunset until midnight. The distance of propagation is 56 km and the wave-length 216 m. It is found that the type of polarisation changes very rapidly—an appreciable change taking place in half a second. The commonest form of polarisation observed approximates to a circle, but straight lines and narrow ellipses often inclined to the vertical plane of propagation are frequently observed. Although the type of polarisation varies considerably, it has been found that the sense of rotation of the figure is always the same. Observations on five different nights and on three different settings of the calibration apparatus have shown that the sense of rotation is anticlockwise if we look along the ray in the direction of travel.

These preliminary results therefore confirm the previous results of Appleton and Ratcliffe, and lend support to the theory outlined by them and recently mentioned by Prof Appleton.<sup>2</sup>

### Perception of Gravity by Roots of *Vicia Faba*

UNTIL recent years it was a generally accepted view that the region of perception of gravitational stimuli in roots was the extreme tip of the root. Cholodny,<sup>1</sup> however, performed experiments in which he replaced the root tip in maize by the tip of the coleoptile, and the fact that a positive curvature was still obtained suggested that the function of the root tip might not be so simple as had hitherto been supposed. More

recently, Keeble, Nelson, and Snow<sup>2</sup> performed experiments in which positive geotropic curvatures were obtained when unstimulated root tips were stuck on to stimulated root stumps which had been decapitated before stimulation

It was pointed out to me by Dr T A Bennet-Clark that opposite stimulation of root and stump would give more exact information of the functions of tip and stump in the perception of gravity Accordingly, four parallel series of experiments, using seedlings of *Vicia Faba*, were carried out, as follows (about forty seedlings being used in each series)

(a) A number of roots were decapitated and placed in a horizontal position in a damp chamber for 3-4 hours, after which these roots were re-headed with tips from other roots which had also been stimulated in a horizontal position for the same period of time These tips were stuck on in such a manner that the side of the tip which had been lowest during stimulation was exactly *opposite* the side of the stump which

FIG 1—A—Diagrammatic representation of a root in series (a) B—Diagrammatic representation of a root in series (b) The thick black line indicates the under side of the root during stimulation, and the dotted line indicates position of root after response

had been lowest during stimulation (Fig 1, A) The roots were then placed in a vertical position

(b) A number of roots were treated similarly to those in series (a), but the new tips were stuck on in such a manner that the side of the tip which had been lowest during stimulation was on the *same* side as the side of the stump which had been lowest during stimulation (Fig 1, B)

(c) The roots from which the tips had been cut to re-head series (a) were also placed in a vertical position

(d) Normal roots were stimulated and then placed in a vertical position

The results obtained were as follows

Series a 67.5 per cent curved towards the side of the tip which had been lowest during stimulation  
15 per cent curved towards the side of the tip which had been uppermost during stimulation  
17 per cent remained straight

Series b 70 per cent curved towards the side which had been lowest during stimulation  
30 per cent remained straight

Series c 63 per cent gave a positive curvature  
37 per cent remained straight

Series d 70 per cent gave a positive curvature  
30 per cent remained straight

From the results of series (a), it can be seen that, in decapitation experiments with *Vicia Faba*, the root tip has a much stronger directional influence on response to gravity than the root stump The results of series (a) are seen to be significant, since the per-

centage response obtained in the control series (b), (c), and (d) is of the same order as that in series (a)

It is hoped that a full account of this work will be published later

### Molecular Structure of Cellulose and of Amylose

FROM the purely chemical properties of cellulose, recent experiments have enabled us to gain further information as to the nature and length of the cellulose chain It will be remembered that earlier work from this Laboratory showed that cellulose contains repeated units of  $\beta$ -cellobiose, and the present views on the intimate structure of this polysaccharide are based on these researches published in 1925-27

We have now obtained evidence that cellulose, in the form employed in our experiments, is a straight chain of limited length containing not more than 100 cellobiose units or 200 glucose units This represents a molecular weight of about 30,000 The lower possible limit is 25,000

This result was attained by preparing in one operation completely methylated cellulose from its acetate and submitting this to hydrolysis with aqueous hydrochloric acid at 0° The cleavage products from 200 gm yielded almost quantitatively the methylglucosides of the methylated glucose fragments, and by fractional distillation under diminished pressure, using a special column, a yield of 0.55 per cent of tetramethyl methylglucopyranosides was obtained. The remaining fractions consisted only of 2, 3, 6-trimethyl methylglucosides

Control experiments were conducted by distilling an artificial mixture of 2, 3, 4, 6-tetramethyl methylglucosides and 2, 3, 6-trimethyl methylglucosides and determining the quantity of the former which was separable This was found to be almost quantitative

It is clear, therefore, that in our specimen the cellulose chain was not endless, since to the extent indicated above, one of the glucose units formed an end group containing one more methyl residue than did the intermediate members It was thus possible to assay this component by quantitative methods, and hence determine the molecular size of the cellulose derivative This evaluation corresponds very nearly to that derived by Svedberg's method for the high polymeric forms of a number of natural products Dr H Machemer has collaborated with me in this work

Applying this procedure also to the amylose portion of starch, we have found that a much larger proportion (5 per cent) of the tetramethyl glucose component can be recovered by hydrolysis of completely methylated amylose This result, on the above interpretation, corresponds to only ten maltose units or twenty  $\alpha$ -glucose units in a chain which is not endless, or a molecular weight of not more than 4000. This conclusion is unexpected, and we are led to believe that similar experiments on the amylopectin portion of starch will yield a much higher value for the molecular size Dr E L Hurst, Dr M M T Plant, and Miss Wilkinson are specially identified with this work

We are reserving the application of this experimental method to glycogen, inulin, xylan, and other types of polysaccharides, and this work is already in hand

## Research Items

**Australian Female Skull**—Prof F Wood-Jones points out in *Man* for February that the statement frequently made that 1000 cc is the lowest capacity occurring in skulls that can be classed as normal and human is erroneous. The female Australian skull is not only remarkably small, but also falls below this figure. It is due to this misconception that the discovery of a female Australian skull of 960 cc was hailed with such enthusiasm as having the lowest known cubic capacity of any human skull (MacKenzie). Hrdlička's average for 395 female crania is max length 179.4, max. breadth 127.6, basibregmatic height 127.4, modiolus, 144.8. Among these normally small-headed females there is a very definite element, especially in the central-northern and western portions of Australia, of unusually small-headed women. Sir William Turner, in his *Challenger* report (1884), found in 11 skulls an average cranial capacity of 938 cc, while in 30 adult Australian female skulls with a modiolus of 139 or less, which were measured by Hrdlička or the writer, the averages were as follows—max length 169.7, max breadth, 120.7, basibregmatic height, 121.9, modiolus 137.5. Although the capacity was not measured directly, some guide to the relation between the modiolus and the cranial capacity is furnished by the following correlations

| Designation of Skull | Modiolus | Measured Capacity |
|----------------------|----------|-------------------|
| M U Wimmara          | 132.3    | 900 cc            |
| Sir W Turner, avge   | 135.0    | 938 cc            |
| M U 54, 94, 5, 37    | 138.3    | 960 cc            |

The so-called 'Jervois' skull, which has no claim to antiquity, yields a modiolus of 139.3, and a cranial capacity, measured (MacKenzie) 956-980 cc. It cannot, therefore, be regarded as a remarkably small Australian skull. It exhibits no craniological characters which differentiate it from the accepted standards of the normal recent female Australian skull.

**Prehistoric Domestic Pottery from Southern India**—Mr L. A. Cammidge describes in the *Indian Antiquary* for February pottery from some ancient soak-pits found in old and now exhausted brickfields at Chetput, Madras. Fragments of pottery of urn-burial types were found scattered over an area of ten acres at the bottom of clay pits at a depth of 15-20 ft below the present ground level. They were derived from the bottom of silted-up wells which had been 24-30 inches in diameter. The wells had been constructed of pottery & in thick made in sections about sixteen inches in height, flanged at the base, and curved slightly inward at top. Wells of this type are not now made. In two wells examined there were about four feet of broken pottery mixed with bones. The pottery included fragments of large broad-mouthed pots of the usual urn types, and fragments of shallow oval or coffin-shaped troughs about twenty-four inches in length. There was also a large-necked pot of unusual type about thirty inches in diameter. Most of the smaller pots had globose bodies with narrow vertical rimless necks. Some had six holes at the base of the neck for suspension. Finally, there were fragments of polished red ring stands about ten inches in diameter. The importance of these types from the wells, or rather soak-pits, is that they represent domestic pottery—differing in certain respects from the funerary pottery—of the cist and urn-burial period, which has not hitherto been studied.

**'Flying Foxes' in Australia, and their Economic Significance**—The Australian Council for Scientific and Industrial Research, in *Bulletin* No 53, has published a work of extraordinary interest to the naturalist, embodying the results of co-operative investigations between different State departments, correlated and controlled by F. N. Ratcliffe. It is shown that, contrary to general belief, flying foxes (large bats of the genus *Pteropus*, some measuring almost four feet from wing-tip to wing-tip) are not a serious menace to the commercial fruit industry, and since the numbers are much greater than had been supposed, the serious control of the various species is regarded as beyond compass at reasonable cost. But we turn rather to the natural history of these bats. They live in 'camps', and a typical Queensland 'camp' during the day, when the animals hang asleep upon the trees, covered 5-10 acres of rain forest. When the camp rose for the night at 6 P.M. it formed a great column, about 100 yards wide and 100 feet deep in the centre, which continued to spue itself out of the trees continuously for 25 minutes. The number of bats was estimated (with great care) at about 220,000, and this was a small camp. A really large camp on Red River was half a mile wide and about four miles long, and the bats were present in millions. It seems likely that Australia was originally colonised by the bats by way of the Cape York route, but at a period remote enough to have allowed the specific differentiation of the five Australian forms.

**Parasites of the Wheat-Stem Sawfly in England**—The wheat-stem sawfly (*Cephus pygmaeus*) is of negligible importance as a pest of cereals in England. On the other hand, the closely allied western wheat-stem sawfly (*C. cinctus*) is a very serious enemy of the wheat crop in western Canada. The English species appears to be heavily parasitised, and it is likely that one or the other of its parasites might prove suitable for introduction into Canada. Little, however, was known respecting the economy of *C. pygmaeus* until the matter was studied by Dr G. Salt of the Imperial Institute of Entomology (*Bull. Entom. Res.*, Dec. 1931). As the result of his investigations he finds that several species of hymenopterous parasites attack *C. pygmaeus*, and one of them, the ichneumon fly, *Collyria calcitrator*, is of major importance. This insect attacks and destroys its host so heavily that it is evidently a highly important factor in the control of the stem sawfly under English conditions. Dr Salt describes the life-history and figures the larval stages of this and other *Cephus* parasites. From the economic point of view, however, the *Collyria* appears to be the only one of primary importance. Its perfect adaptation to and complete concentration on wheat-feeding *Cephus*—its independence of alternative hosts—its ability, as indicated by its wide range, to exist under different climatic conditions—all these factors give promise that its introduction into Canada will lead to beneficial results. This conclusion led to Dr Salt directing the collection of many thousands of *Collyria calcitrator* and their shipment to the Dominion Parasite Laboratory at Belleville, Ontario. The handling and transmission from Belleville to western Canada of this material was superintended by Mr C. W. Smith of the Dominion Entomological Branch. Liberations were made in suitable areas in Manitoba, and a short paper on the experiment is contributed by Mr Smith in the same issue of the journal already mentioned. Since the actual liberation only took place in 1930 it is pre-

mature to forecast its results. It is encouraging, however, to note that Mr Smith finds that the parasite has shown itself capable of attacking the Canadian *Cephus* and has succeeded in establishing itself.

**Potato Sickness**—The peculiar disease of potatoes known as 'sickness' has baffled students of plant pathology, but we have now a very definite pronouncement on the subject ("Potato Sickness", by W A Millard, S Burr, and L R Johnson, *Gard Chron*, Jan 9, 1932, p 28) as the result of co-operative study by the zoologists and botanists of the University of Leeds Agricultural Department. The cause of the sickness has been previously ascribed to two different fungus diseases as well as to eelworm injury, so the experiments under review were designed to test the effect of these three agencies, both singly and in different combinations. Photographs of typical plants which are published with the account show that only when eelworms (*Heterodera Schachtii*) were inoculated on to the plants did symptoms of 'sickness' appear. It seemed to matter little whether fungi were inoculated along with the eelworms or not, so it is concluded that the disease in question is caused by the latter agents. It is pointed out, however, that under field conditions the fungus *Corticium solani* may aggravate the malady.

**Cambrian Conchostraca**—E O Ulrich and R S Bassler have completed an important and detailed investigation of those small Cambrian Crustacea, most of which have been referred previously to the Ostracoda, in their publication "Cambrian Bivalved Crustacea of the Order Conchostraca" (No 2847 *Proceedings of the United States National Museum*, vol 78, art 4, 1931). The authors show that these certainly do not belong to that superorder but rather to the Branchiopoda. A scheme of classification is given which includes the Cambrian Conchostraca and allied genera, and it is suggested that the Ostracoda were derived from the earlier Bradonidae and Beyrichonidae. The chief differences are the position of the main muscle spot, the composition of the shell, and the incomplete separation of the valves. In the Bradonidae the margins of the valves, except along the back, are apart, the edges being so opposed that a narrow slit separates them. The illustrations to this monograph have been very carefully prepared, most of the figures being photographs which have been touched up slightly, the specimens having been whitened by the ammonium chloride process before being photographed. The result is excellent and the ten plates show up the specimens in a most satisfactory manner.

**Philippine Earthquake Epicentres**—The Rev W G Repetti, S J, Chief of the Seismic and Magnetic Division of the Manila Observatory, has written a valuable report on the epicentres of the Philippine earthquakes (1920-29) that lie north of Manila or lat 14° 30' N (*Manila Seismological Bulletin for 1930*, pp 71-85, 1931). None of the earthquakes considered was of destructive violence, though some were strong enough to crack walls. The earthquakes (300 in number) are divided into four groups according to the accuracy of the determinations. They lie almost entirely in the western part of Luzon and in the China Sea. The submarine epicentres lie along four lines, the most important of which is about twenty-eight miles off the west coast and in its southern portion is parallel to it. It lies along the eastern and steeper slope of the Abra Deep, a basin that rapidly descends to a depth of more than three miles.

**Uraninite from Henvey Township, Ontario**—H S Spence has described an occurrence of uraninite with thucholite, cyrtolite, and oily hydrocarbons from the

Besner pegmatite in the Parry Sound District (*Am. Mineral*, Nov 1930). Three analyses of the uraninite by H V Ellsworth appear in the same journal for last December. Among the results are the following

|           |       |       |       |
|-----------|-------|-------|-------|
| U         | 68.29 | 67.26 | 67.30 |
| Th        | 1.56  | 1.52  | 1.85  |
| Pb        | 8.04  | 7.51  | 7.57  |
| Pb        |       |       |       |
| U+0.38 Th | 0.117 | 0.111 | 0.111 |

The material has evidently been somewhat altered, but, in view of his work on the Villeneuve uraninite, Ellsworth concludes that the alteration of the Besner uraninite has not gone far enough to render the lead-ratio unreliable and that the true age is indicated by a value between 0.11 and 0.12. The granites with which the pegmatite is associated have been regarded by Quirke as Killarnean (latest pre-Cambrian granitic intrusions), but it is pointed out that whereas indubitable Killarnean granites have  $K_2O > Na_2O$ , the Henvey Township granite has  $Na_2O > K_2O$ . In this respect the latter granite resembles those of the Grenville sub-province for which lead-ratios of 0.15-0.16 are typical. It is therefore by no means certain that the Henvey granite is of Killarnean age.

**Selective Heating by Short Radio Waves**—The November number of the *Canadian Journal of Research* contains a paper by Prof J C McLennan and A C Burton in which a general theory of the heating of an object in the condenser of a high-frequency circuit is developed, and the essential result of the theory, that the action is selective for electrical as well as thermal reasons, is demonstrated by a number of ingenious experiments. With meat, the change in temperature was followed with a paint which changes colour on heating, and it was shown that different parts of this behaved quite differently on changing the wave-length of the oscillations from 10 metres to 25 metres. Eggs and chicken embryos were examined by a thermojunction method, and the white and yolk of a broken egg with a mercury-in-glass thermometer. The last case, again, showed a definite reversal of the effectiveness of this method of generating heat as the frequency was changed from 10 metres to 190 metres, and this was also found to occur with calves' liver and heart *in vitro*. The possible importance of this selective action in medical application must of course depend on the rapidity with which equalisation of temperature can be brought about in living tissues, and can only be settled by direct experiment.

**The Raman Effect**—The second December number of the *Physical Review* contains a valuable account from Prof R W Wood of his technique for producing Raman spectra by the light from a mercury arc. This is inferior in some ways to helium excitation, but is in general far more convenient, since mercury arcs are readily obtained from commercial sources. Prof Wood mounts the arc beneath the tube containing the substance to be studied, with intermediate colour filters, these appear to be essential if unambiguous results are looked for. The light is concentrated by making a liquid filter also serve as a cylindrical lens, and by having a metal reflector on top of the tube holding the substance under investigation. A critical account is given of the Raman spectra of a number of aromatic compounds, and the important observation is made that the presence of several faint lines which are now recorded with certainty for the first time apparently depends upon the actual wave-lengths used to excite them.

**River Pollution**—We have received the Report of the Water Research Board for the year ended June 30, 1931 (London: H M Stationery Office,

9d net) The report deals with the flow of water from the upper Tees and movements of water in the estuary and tidal portions of the river below Stockton, and the effects on plant and animal life, particularly fish. The death of fish caused by the water was shown to be partly due to toxic substances in the water, including phenol and other tar acids, hydrocarbons such as naphthalene, and in some cases cyanides in concentrations found to be lethal to smolts under experimental conditions. The breakdown of sewage in the river has also been studied. In summer the river purifies itself more rapidly and completely than in winter. In summer the river is practically purified about six miles from the point where the sewage enters, whilst in winter the self-purification may not be complete before the industrially polluted zone is reached. The Board puts forward suggestions for improving matters, among them that manufacturing processes should be modified so that no polluting effluents need be discharged. Several authorities in industry have, it is stated, expressed the opinion that in addition to avoiding pollution, the costs of making the necessary modifications for the re-use of part of the water are at least counterbalanced by the resulting economies.

**Tannins and Fatty Acids in Hops**—The true nature of the so-called tannin constituents of hops has always been a matter of doubt, but the results of work published in a recent series of papers by L.

Heintz (*Wochenschrift für Brauerei*, 48, 315-335, 1931) even imply that hops contain no true tannin at all. The hops were first extracted exhaustively with ethyl ether and then with 95 per cent alcohol, and the residue after evaporation of the extract, which constituted 15 per cent of the original weight, was tested for tannins. It was found to reduce Fehling's solution and to precipitate cinchonine sulphate solution, though on the other hand it contained about two per cent of nitrogen, whilst other tannin reagents gave inconsistent results. The cinchonine, ferric chloride, and other reactions for tannins are criticised, but it should be pointed out that so far as actual determinations of tannin are concerned the cinchonine sulphate method proposed by Chapman in 1907 has always given consistent and satisfactory results. Hops stored in warm surroundings sometimes develop rancidity, and the author suspected that this was derived from non-resinous substances, probably fatty acids, extracted in petroleum spirit from the stalks of the ground hops. He therefore separated them from the resins by esterification in ethyl alcohol, neutralisation, and removal from the resin soaps in petroleum spirit. As a rule, 1 to 2 per cent of fatty acids were obtained, according to the nature and age of the hop, about 90 per cent of which were soluble in petroleum spirit and appeared to be oleic acid, whilst the remainder contained saturated acids. In addition, about 1 per cent of neutral unsaponifiable matter was isolated.

### Astronomical Topics

**Atmospheric Changes and Climate**—Dr R. T. A. Innes contributes a paper on this subject to *Scientia* for January. He points out that the former presence of glaciers in many places that are now too hot for them indicates secular changes of climate. He considers that changes in the amount of solar radiation would be compensated by increased cloud formation, and would not greatly affect the surface temperature. He assigns more weight to small changes in the chemical composition of the atmosphere, especially to the percentage of carbon dioxide in it, the large amount of coal, etc., that is now burnt would have some slight effect on this percentage. Dr Innes thinks that some gas may have been introduced into the atmosphere by collisions with comets. The density of the comae of comets is known to be very low, so a very long period of time would be necessary for the introduction of any appreciable amount of gas from this source.

A Science Service Bulletin, dated Jan. 8, describes a study of the atmosphere and the importance to life of the small percentage of carbon dioxide, this is by Dr W. J. Humphreys, of the United States Weather Bureau. Carbon dioxide is essential to plant life, and that, in turn, is directly or indirectly the necessary food of animals. He further explains the importance of the layer of ozone in the upper air. If it were removed, the excess of ultra-violet radiation would be injurious to the eyes, while a great excess of ozone would stop all ultra-violet radiation, which would also have an injurious effect on life.

Dr Maud W. Makemson is making a research of a somewhat similar character at Rollins College, Florida (Science Service Bulletin, Jan. 12). The air in that district is free from contamination by smoke, etc., she takes advantage of this to collect meteoric dust in pans, placed on a high tower, "the fragments resemble volcanic glass or obsidian, while in colour they range from clear glass to amber." She

proposes to continue the research for some time, and to correlate it with the number of meteors observed in the different months by the American Meteoric Society.

**The Expanding Universe**—Mr M. E. J. Gheury de Bray contributes a note to *Astr. Nach.* 5844 in which he points out that Mr Van Maanen's photographs of the spiral nebulae appear to indicate both a rotational and an outward motion in the bright condensations in the outer whorls of the spirals. Van Maanen's results have been criticised as being probably too large, but they are likely to give the correct direction of motion. There is a difference of opinion whether the outward motion of the spirals as a whole extends to the individual members of each spiral, Prof. de Sitter holds that it does, Sir Arthur Eddington that it does not.

It will need a much longer time before Mr Gheury de Bray's suggestion of a general rotational movement of the system of spirals can be verified. In any event, it could be verified only if the angular velocity varied with the distance. He suggests that the angular velocity increases with the distance, but gives no reason to support this, and it appears improbable.

**The Red Spot on Jupiter**—This spot has been in existence at least since 1879, but has varied greatly in visibility, being at times scarcely traceable except by the bay that it produces in the neighbouring belt. Some drawings taken by M. R. Cheveau about a year ago are reproduced in *L'Astronomie* for January. The spot appears to have been plainly visible, though somewhat paler than the adjacent region of the belt. Two of the drawings show a dark stripe across the spot from north to south, suggesting a tendency to divide into two, the other two drawings do not show this stripe, though one of them is intermediate in time between those showing it.

## British Industries Fair

THE British Industries Fair, 1932, to which brief reference was made in our issue of Feb 20 (p 273), has again provided a most striking and significant visual demonstration of the extent, range, variety, and excellence of British manufactured products. It would be futile to attempt, within the limits of a short article, to review the exhibits shown at Olympia and the White City, in London, and at Castle Bromwich, in Birmingham. We must be content to note certain features, likely to be of special interest to readers of NATURE, of the scientific exhibits in the general section at Olympia. Before we come to particulars, however, it may be worth while to emphasise a point that was made last year in our review of the 1931 Fair.

The convenient arrangement of grouping the exhibits according to industries necessarily created a succession of mass effects, with the result that the visitor (who, it will be remembered, was primarily a buyer) could not escape receiving, even if only sub-consciously, a general impression of each particular industry as a whole. No visitor going through the Fair could fail to get, for example, from the china and glassware displays, a vivid impression of the vigour and efficiency of the respective industries, apart from, or rather in addition to, the individual effects created by the exhibits of the several firms. In this connexion the British scientific instrument manufacturers who displayed their products at Olympia are to be congratulated on having achieved, in this mass effect, a still further advance upon the very remarkable advance they made last year. They will do better still next year in the measure that the individual firms in the industry realise the importance of, and their responsibility for, creating a good psychological impression of what the industry as a whole is like.

To come to some of the individual exhibits, Adam Hilger, Ltd, demonstrated, among other things, the textile mutochrome and the blancometer. The mutochrome is a projection lantern device by means of which the colours and shades of individual portions of a pattern or design can be changed at will. Thus a large number of colour compositions of a design can be rapidly investigated and selection can be made of those most pleasing or appropriate for a given purpose. The instrument is finding increasing use in the textile industries. All the experimental work previously requiring the production on the loom of a collection of mixed patterns, from which choice might be made, can be done with the mutochrome in less time and without waste of material. The design is projected on a screen so that it may be viewed simultaneously by a number of observers, not only the colour but also the brightness of each element of the design may be altered independently, the colour variations being obtained by the use of colour filters, and variations of shade or brightness by means of calibrated iris diaphragms. The blancometer is an instrument designed for the accurate numerical specification of nearly-white colours. Its chief applications are to papers, fabrics, paints, powders, and other raw materials and products of industry where fine discrimination is required between nearly-white specimens. By its aid it is possible to measure accurately, without the interposition of a visual judgment, the amount of light of different portions of the spectrum reflected from a sample under test, compared against light reflected in precisely similar circumstances from a standard white surface.

Among the exhibits of Ross, Ltd, were an educa-

tional cinematograph projector for use in schools and institutions, and a new epidiascope. Special features claimed for the cinematograph projector are the great amount of light transmitted and the steadiness of the picture. Cooling by blower is so efficient that, with the full light on, the film can be stationary for hours without detrimental effects. It also embodies all the necessary precautions against fire prescribed by the L.C.C. regulations. A novel feature of the epidiascope is that it has a single lamp capable of yielding 500 watts or 1000 watts as desired. By the single movement of a lever the instrument can be changed from diascope to episcopes, or vice versa. The whole instrument is made to slide easily over the book or other object under projection, so that various parts of the object may be shown. The lenses for episcopes and diascope are anastigmats, and there are various attachments to facilitate micro-projection and standard film projection.

R. and J. Beck, Ltd, showed, besides types of their well-known microscopes, a high power binocular attachment for the microscope. It is claimed that the design of this attachment renders it suitable for use with any type of monocular microscope, without the disadvantage of increasing to any great extent the working height of the instrument. The optical principle permits as well any power of object-glass or eyepiece as any type of illumination to be employed. There were also to be noted a new pathological microscope and an eyepiece camera by this firm. To give great rigidity, the base and pillar of the microscope are in a heavy solid casting with large spread ( $7\frac{1}{2}$  in  $\times$   $5\frac{1}{2}$  in), enabling the microscope to stand firmly in either the vertical or the horizontal position.

The Thermal Syndicate, Ltd, exhibited a remarkable fused quartz celostat plano-mirror, eighteen inches in diameter. The blank had been manufactured by the firm and then ground, polished, and silvered by Sir Howard Grubb, Parsons and Company. Another noteworthy exhibit of the Thermal Syndicate was a vitreosil (pure fused silica) sunshine lamp. The lamp has been designed to provide a very close approximation to sunshine, including that proportion of ultra-violet radiation which is now known to have an important beneficial effect on human health. The approximation to true sunlight is produced by balancing the blue-green of the mercury arc with the correct amount of the light from gas-filled filament lamps, which has an excess of yellow and red. The vitreosil bowl of the sunshine lamp filters out the shorter ultra-violet rays, that is, below approximately 2950 Å, but allows the rays of the near ultra-violet, which are present in sunshine, to pass freely. Another effect of the vitreosil bowl is to eliminate glare.

Of the interesting exhibits of the chemical sections we must be content to mention two novelties shown by Imperial Chemical Industries, Ltd. This organisation has produced the 'pioneer partition block' for the construction of partitions in modern buildings, in the ways that breeze blocks are used. It is claimed that the mineral from which the blocks are made is highly standardised and unusually inert; it does not soften, move, or deteriorate with variation of humidity or with actual wetting, and, chemically, in the sense of attack on paints and pigments, it is safer than any other analogous material yet used. The other exhibit was a demonstration of the use of solid carbon dioxide as a refrigerant. This product, marketed under the name of 'Drikold' by the Imperial Chemical

Industries, Ltd., has a density 1.35-1.45, and evaporates slowly without melting, to give a tasteless, odourless, non-poisonous, and incombustible gas. It has a temperature of  $-110^{\circ}\text{F}$ , and is being largely used as a refrigerant in the ice-cream industry, in road and rail transport, and in the dairy industry.

Limitations of space preclude the mention of any of the many other scientific exhibits. One impression produced by these exhibits may finally be noted, namely, the growing application to industry of instruments previously regarded as appropriate only to the academic field.

### Scientific Publications in 1931

REFERENCE has been made from time to time in notes and articles in our columns to the ever-increasing flood of books and other publications with which scientific workers have to cope. Apart altogether from the question of expense—and that has become serious enough, as letters in *NATURE* a few years ago can testify—even the specialist has difficulty

in finding time to keep up with the literature of his own department of work. If any confirmation of these statements be required, it is given in Table I. This has been compiled from the monthly lists of "Recent Scientific and Technical Books" published in *NATURE* during 1931 and represents, roughly, a year's output of priced scientific and related publications; it does not include periodicals. The entries have been classified by subject and country of origin, and volumes actually received by *NATURE* for notice are marked by an asterisk. Turning first to the totals at the bottom of the table, it will be seen that the titles of 3227 publications were recorded in the *NATURE* Supplements during 1931, of which no less than 1357 were actually received at *NATURE* Office for notice. In-

in finding time to keep up with the literature of his own department of work.

If any confirmation of these statements be required, it is given in Table I. This has been compiled from the monthly lists of "Recent Scientific and Technical Books" published in *NATURE* during 1931 and represents, roughly, a year's output of priced scientific and related publications; it does not include periodicals. The entries have been classified by subject and country of origin, and volumes actually received by *NATURE* for notice are marked by an asterisk. Turning first to the totals at the bottom of the table, it will be seen that the titles of 3227 publications were recorded in the *NATURE* Supplements during 1931, of which no less than 1357 were actually received at *NATURE* Office for notice. In-

Turning now to the 'cross-totals', which show the numbers of scientific and technical publications issued by various countries, the lead is taken by Great Britain with 1488, but Germany makes a good second with 1138, the total for the United States is 346, and the aggregate for the other countries listed is 255. Thus, according to the titles shown in our Supplements, Great Britain is responsible for about 46 per cent, and Great Britain, Germany, and the United States together for about 92 per cent of the world's scientific and technical publications.

Table II has been compiled from the indexes of the last two volumes of *NATURE* and shows the number of publications actually noticed in our review columns during 1931. The subject classification here differs slightly from that in Table I, but will serve to

show that the number of volumes noticed in a particular field follows roughly the number published, thus mathematics and physics heads the subject list of publications both as regards number published and number received for notice, and a larger number of

TABLE II—BOOKS REVIEWED IN NATURE DURING 1931

works on these subjects were noticed in our columns. It is also worth noting that while mathematics and physics claims 22 per cent of our review notices, biology comes second with 16 per cent.

The total number of publications reviewed during the year also requires comment. This number, 672, does not include the numerous references to publications made in "News and Views", "Research Items", "Astronomical Topics", "University and Educational Intelligence", and also in articles, many such publications are included in Table I. Hence we are justified in saying that considerably more than one-half of the publications received by NATURE are dealt with in our columns.

### Stock Diseases and Poisonous Plants

A PAPER upon the "Poisonous Action of Ingested Saponins", published as *Bulletin* 50 by the Council for Scientific and Industrial Research of the Commonwealth of Australia, has very general interest to stockbreeders and all who are interested in obscure diseases of stock in various parts of the world.

Prof A. J. Ewart, of the University of Melbourne, suggests that various obscure stock diseases of Australia, America, New Zealand, and South Africa, like the 'walkabout disease' of horses in Australia, may be caused by the saponins present in the tissues of plants on which the animals graze. In the case of the 'walkabout disease', Prof Ewart, in conjunction with Mr D. Murnane, in 1927, produced the disease in six horses by feeding them, for periods of a month or more, with *Atalaya hemiglaucæ*, a plant rich in a hæmolytic saponin. Later, however, Dr Seddon found that horses could be fed on fresh leaves of this plant for many months, in New South Wales, without any symptoms of disease developing.

Prof Ewart now shows that, whilst the plant grows abundantly down to the twenty-fifth parallel, 'walkabout disease' only appears north of the nineteenth parallel. The reason seems to be that in the more southerly latitudes this plant contains less saponin and more of a tannin which protects against the hæmolytic action of the saponin. Tests of saponins by intravenous injection or by hæmolysis experiments

are both difficult and expensive. Prof Ewart shows that very good evidence of the toxic nature of the saponin (or extract) under investigation may readily be obtained by the use of the water snail *Bulimus*. Only plants containing a relatively higher percentage of saponin are likely to prove toxic, and then under conditions providing for continued grazing on the plant, as the saponins do not dialyse readily and only a small fraction of the ingested saponin is absorbed in the alimentary canal. This percentage absorption is increased by the use of purgatives or by inflammation of the alimentary canal. Species of *Solidago*, *Aster*, and *Senecio* are amongst the plants suspected of producing diseases of stock from this cause, the percentage of saponin in the dry leaves varying from 2 to 8 per cent in these species.

The Winton diseases of horses and sheep in New Zealand, characterised in chronic cases by pronounced cirrhosis of the liver, can be produced artificially by continuous feeding on the ragwort, *Senecio Jacobææ*.

### Post-Glacial Prehistory in Ireland

OUR knowledge of the post-glacial prehistory of northern Ireland is summarised by Mr C. Blake Whelan in a recent communication to the Société Préhistorique française (*Bull.* 1931, 7-8). Although Chellean and Acheulean do not appear, it is possible to find in the gravels of north-east Ireland rare and doubtful specimens which appear to be humanly worked and may be examples of a pre-Mousterian, or even older, culture. The interesting Clactonian station of Rosses Point, Sligo, is an example. Yet up to the present, undoubted evidence of a true Mousterian of the Laufen interval between Wurm I and II appears to be lacking. Man may have retreated southward and not returned until the great glaciations had definitely retreated from Ireland.

The same uncertainty obtains regarding post-Wurm II. The only undoubted Aurignacian station is on Rathlin Island. There may also be a true Aurignacian tradition in the implements from below the ancient flood level of the lower Bann. Although of undoubted antiquity, it is difficult to bring such finished specimens into relation with the crude implements which follow. To the Buhl-Gshnits interval belong a series of a palæolithic industry of remarkable facies from the 50 ft raised beach of Antrim (see NATURE, July 26, 1930, p. 133), which may belong to a period anterior to the Baltic Lake. It may be a belated Magdalenian or a new industry, but it has nothing in common with the European microlithic culture extending from the Reindeer period to the Maglemose. The period in Ireland really corresponding to the Baltic Lake is found in the peat at the base of the deposits of the estuary of the Lagan (Belfast), which are covered by an ancient estuarine clay, itself underlying the gravels of the 25 ft raised beach.

In an analogous deposit at Larne is an industry thought to represent the final phase of the northern Magdalenian (see NATURE, Sept. 6, 1930, p. 352). In the 25 ft raised beach are found 'Asturian picks' mixed with a great quantity of roughly made implements which in the north are contemporary with the decline of the Magdalenian in the south-west. These may be the work of a race of pre-Mousterians driven north by the Aurignacians. At Glenarm is the pre-Campignian transition, and at Strangford Lough a number of stations mark the arrival of the true Campignian. Then comes the hiatus, followed by the neolithic and chalcolithic ages with their implements of classic upper palæolithic types, the final puzzle of the Irish stone age.

## University and Educational Intelligence

**BIRMINGHAM**—At the annual meeting of the Court of Governors held on Feb. 25, the vice-chancellor (Sir Charles Grant Robertson) stated that the University is making special efforts to forward the study of biology by increasing the supply of competent teachers available for schools and universities. He directed attention also to the highly successful work of the Appointments Board, the annual number of posts found by this board for Birmingham graduates having increased from 226 in 1924 to 346 in 1930, making a total of 1727, at a cost of about £100 a year. The economical working is due largely to the co-operation of the staff.

Prof. W. S. Boulton, professor of geology since 1913, is retiring at the end of the present session.

**CAMBRIDGE**—J. O. Girsavicius (Gonville and Caius College) has been appointed to the Benn W. Levy research studentship in biochemistry for one year.

**LONDON**—The following degrees have recently been conferred: D.Sc. (Botany) on Mr. M. A. H. Tincker, for seven published works dealing with the physiology of economic plants, together with four subsidiary contributions; D.Sc. (Physics) on Mr. F. H. Schofield, for eight published works on thermal conductivity and precision measurements of high temperatures, together with three subsidiary contributions; D.Sc. (Geology) on Mr. R. W. Pocock (Birkbeck College), for a thesis entitled "Contributions to the Geology of the West Midlands", consisting of four papers (*Geol. Survey*, 1921 and 1925, and *J. Geol. Soc.*, 1930–31).

THE result of the appeal made last year to former students of the Heriot-Watt College, Edinburgh, and friends and colleagues of the late Sir Francis Grant Ogilvie, the first principal of the College, has made possible the establishment of a Grant Ogilvie Memorial Prize Fund. The income of the Fund will provide two prizes, which will be awarded annually to the best students in the final years of the diploma course in electrical engineering and chemistry.

A NEW list of holiday courses in Europe has recently been compiled and published by the League of Nations Institute of Intellectual Co-operation, in three languages, English, French, and German (Oxford University Press, Warwick Square, London, E.C.4. Price 1s.). This list of courses open to foreign students contains all the essential information on 135 holiday courses to be held during 1932 in 17 different countries and 82 cities.

DOCTORATES conferred in the sciences by American universities are reviewed year by year for the National Research Council, Washington, and the titles of the theses, arranged under subject group headings, are published with statistical summaries in the Council's Reprint and Circular series. The review for 1930–31 shows that the number of these doctorates has increased steadily since the series began in 1920, from 330 conferred by 31 universities to 1147 conferred by 63. It provides data for what may, perhaps not too fancifully, be called the climatology of scientific research. Chemistry, as usual, claims a third of the aggregate of the labours of the new doctors—in Ohio State University, Columbia, and Illinois, one-half. Next to chemistry comes zoology, in which from fifteen to twenty per cent of the doctorates were conferred in California, Harvard, Johns Hopkins, Iowa State College, Michigan, Wisconsin, and Yale. Next in order come psychology, physics, botany, mathematics,

each of which is responsible for more than seventy doctorates, followed by physiology, agriculture, geology, bacteriology, pathology, engineering, and public health. Of the twenty theses on public health subjects, no less than sixteen belong to Johns Hopkins University. In the lists of titles, students will find indications of the lines of research favoured in America, that, for example, much of the research in psychology is concerned with observations of conditioned reflexes in white rats. Cancer research is conspicuous by its absence from the lists. Looking back over the records of ten years, the only important exceptions to the general increase by two hundred or more per cent in the number of doctorates conferred under the several subject group headings are physics (160 per cent), geology (170 per cent), and pathology (decrease by 4 per cent).

## Calendar of Geographical Exploration

March 7, 1778—Cook's Last Voyage

Capt. Cook reached the north-west coast of America in about lat.  $44\frac{1}{2}^{\circ}$  N. In the summer of 1776, Cook, in the *Resolution*, accompanied by Charles Clerke in the *Discovery*, had sailed on a voyage of exploration for the British Admiralty to the northern region of the Pacific coast of America, with the view of discovering a route thither via the Arctic. A few new islands were discovered in the Pacific, including the atoll named Christmas Island, where an eclipse of the sun was observed on Dec. 30. On Jan. 18, Hawaii was discovered, and the group was named the Sandwich Islands, after the Earl of Sandwich, who had done so much to encourage Cook's explorations; the Spaniards had probably visited the group in the sixteenth century. The coast of America north of  $40^{\circ}$  N. was practically unknown before Cook's visit. His vessels anchored in Nootka Sound, and thence proceeded north, naming islets and inlets as they went. Cook's Bay was thoroughly explored, and conclusive proof was obtained that no passage through to Hudson's Bay existed. The coast of the Alaskan Peninsula was surveyed, and Cape Prince of Wales reached and named. Crossing the strait to the Asiatic side, Cook made acquaintance with the Chukchee, returned to the American side, and pushed north to Cape Lisburne. Ice on both coasts and in the open sea compelled the vessels to return. On the west coast of Hawaii, Cook was murdered by the natives. Capt. Clerke took charge and decided to continue Cook's work in the northern Pacific, but he died on Aug. 2, 1779, and was buried at Petropavlovsk (Kamchatka). The vessels then returned, reaching the Nore in 1780. Cook's previous voyages contributed so much to exploration that his remarkable achievement in these northern regions is sometimes overlooked.

March 7, 1925—Eastern Bolivia

Col. P. H. Fawcett, leading an expedition to explore eastern Bolivia, reported from Cuyaba, Brazil, that his party was fit and his instruments were in good condition. Fawcett stayed at Cuyaba until April 20, and thence started on his proposed exploration of the Xingá, Araguaya, and Tocantín regions. A dispatch, dated May 30, 1925, from a camp in lat.  $11^{\circ} 43' S$ , long.  $54^{\circ} 35' W$ , was the last that was heard of him and his son and a young Englishman, R. Rimell. G. M. Dyott left for Brazil in 1928 to search for the party, and succeeded in crossing from Cuyaba to the Kulisehu River and thence reached the Xingu, following it to the Amazon. His journey was a remarkable feat of exploration, but it failed to find Fawcett and his party, and Dyott concluded that they had been

murdered by Indians. Fawcett's previous work had included many explorations in Eastern Bolivia, and he had acted as chief commissioner on the Bolivia-Brazil boundary commission in 1906.

March 9, 1914—Capt Shakespear in the Arabian Peninsula

Capt Shakespear reached the Malham oasis, previously unvisited by Europeans. He left Koweit in February, determined to penetrate into the heart of the desert peninsula of Arabia and to cross it from the Persian Gulf to Egypt. He covered some 1200 miles of unknown country, and for the whole of his journey he kept up a continuous route traverse, checked by observations for latitude, he also took hypsometric readings for altitude. Thus for the first time a complete traverse of the lower Wadi er Rumma was achieved, the first reliable map of the Tuwaik settlements was made, and a new route from Buraida to Jauf followed. From 1909, when he was appointed political agent at Koweit, Shakespear had made annual excursions into the comparatively unknown hinterland, and these paved the way for his last journey. In 1915 he was killed in a skirmish between the forces of Ibn Saud and his rival Ibn Rashid.

## Societies and Academies

### LONDON

Royal Society, Feb 25—D M Needham, J Needham, E. Baldwin, and J Yudkin. A comparative study of the phosphagens, with some remarks on the origin of vertebrates. Arginine phosphate exists in all the invertebrate phyla of which representatives were studied, though in the coelenterates it was only found in a ctenophore. This compound may be associated with ciliary as well as muscular movement. Creatine phosphate is not confined to the vertebrates, but was found in echinoderm jaw muscle and enteropneust tissues. If any evolutionary significance may be attached to these findings, it is probable that they support the echinoderm-enteropneust theory of vertebrate descent (Bateson, MacBride, Garstang).—G Philips. Myotatic reflexes in sympathetomised muscle. After excision of its sympathetic innervation, skeletal muscle exhibits quantitative changes in proprioceptive reflex activity. Simultaneous myotatic contractions of two soleus muscles when subjected to the same passive stretch have been recorded by a 'double' isometric myograph and a twin string galvanometer. Three conditions of stretch-stimulation have been regarded as essential in making comparable records. These are, a small passive increment of length, performed at an even rate, from an initial posture of minimal tension. Under such conditions the latent period of the myotatic reflex determined by the time of onset of the first action current wave is shorter in the sympathetomised muscle. Soleus muscle deprived of its sympathetic innervation some weeks previously loses in great degree its power of maintenance of any postural contraction of other than low tension. The available evidence denies the existence of any sympathetic nervous mechanism responsible for the direct qualitative control of postural reactions, and suggests quantitative changes following sympathetomy are produced by a disturbance of the excitability of proprioceptive end-organs in sympathetomised muscle.—J C Eccles and H E Hoff. The rhythmic discharge of motoneurons. The events during the rhythmic cycle are described in terms of the 'activity' of the rhythmic centre, by which is meant the propensity of the rhythmic centre to set up a reflex discharge.

Geological Society, Jan 13—F B A Welch. The geological structure of the eastern Mendips. The area discussed comprises the Beacon Hill pericline, the most southerly situated of the four echeloned Mendip periclinal and that bordering the Radstock coalfield. As in the other three cases, the structure is anticlinal with a steeply folded north limb, the core is formed of Old Red Sandstone and Silurian, the Avonian outcropping on the flanks. The south limb is much concealed by Mesozoic strata, which also stretch across the eastern part of the area, so that the Avonian can only be seen in deep ravines. The whole sequence of events appears to have been the northward drive of the east-and-west pericline against the southern 'nose' of the coal measure basin (with a north-and-south axis). Maximum resistance was offered to this movement along the line of this axis, and in this line lies the central fault block—E S. Hills. Upper Devonian fishes from New South Wales. The greater part of the material comes from Harvey's Range, north-north-east of Parkes, but there is a single specimen from the Jemalong Gap, another single specimen from the western flank of the Canoblas Mountains, and a few plates preserved in limestone from an unknown locality. The faunal list is enumerated. *Remigolepis* is a new genus lately erected by Stensio to embrace remains found in East Greenland, and its presence in the collection was recognised by him. Not only does the present record of Upper Devonian fishes from New South Wales greatly extend the known range of these forms in south-eastern Australia, but also it affords valuable evidence for the correlation of the Devonian rocks of that district. It is suggested that the shallow marine deposits of the Lambian (Upper Devonian) series may be, in the main, older than the continental deposits of that epoch, and that the Upper Devonian rocks of Victoria may be the equivalent of only the top of the series as it is developed in New South Wales.

Physical Society, Jan 15—Shih-Chen T'ao and William Band. Some thermomagnetic effects in nickel and iron. The paper relates to the production of an e.m.f. in nickel and iron wires by the simultaneous application of a longitudinal magnetising field and a temperature gradient.—W A Leyshon. On periodic movements of the negative glow in discharge tubes. The effect is produced when traces of hydrocarbon vapour are present in the tube in addition to the filling gas (neon, in most of the experiments here described). The jumping glow may be due to internal flashing at that part of the surface of the cathode which is not covered by negative glow. The flash may be caused by the electrical breakdown of a partially insulating hydrocarbon layer, as a result of the collection of positive ions, or by a surface chemical action occurring when the reaction products of the discharge have reached a certain concentration at that surface. It is supposed that the electron emissivity of the surface is increased by the flash, and that the main glow jumps to the activated surface. The process is reversible and hence may be periodic.—G I Finch and R W Sutton. A cathode-ray oscillographic method of measuring inductance. The voltage fluctuations across the condenser in a damped oscillatory circuit, comprising inductance, capacity, and resistance, are recorded by means of a cathode-ray oscillograph.—H R Nettleton and F H Llewellyn. On the measurement of electrical resistance in terms of a mutual inductance and a period. It is shown that if the ratio  $a/a'$  of the radii of the concentric circles forming a simple inductometer is 0.50607, the mutual inductance is so accurately proportional to the angle through which the turning coil is displaced that the rising deviation from a linear law is

less than 5 parts in a million at  $7^\circ$  of deflexion. If the outer circle is replaced by two twin circles which are separated symmetrically with regard to the turning coil, the ratio  $a/a$  must be increased to bring about a similar approach to linearity. If a heavy dynamometer is constructed on this principle, then, over the range indicated, the deflecting couple is strictly proportional to the current-products.

## PARIS

Academy of Sciences, Jan 18—E Jouguet Cooled diffusors—L. Cayeux The interpretation of the deposits of magnesian limestone of Bimont (Oise) and of Étretat (Seine-Inférieure) The magnesian formations at Bimont and Étretat have important characters in common. Both appear to have been caused by a local modification of the submarine medium. The hypothesis of modifications of the original limestones by the action of mineral springs charged with magnesium salts can be dismissed—Charles Achard and Maurice Piettre Some physical and chemical properties of the mucine of the synovial articulations—André Blondel Calculations concerning high voltage lines with use of transformers—A Recoura New researches on the hydrated chromic chlorides. Starting with ordinary chromic chloride, usually considered to be  $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]\text{Cl} \cdot 2\text{H}_2\text{O}$ , and drying in a vacuum for three to four days, anhydrous ether extracts a brown chloride which is probably  $[\text{Cr}(\text{H}_2\text{O})_3\text{Cl}_3]$ . A second method, using acetone, is also given for preparing the brown chloride—Rene Maire and Louis Emberger The vegetation of the Anti-Atlas—Ch Porcher and L Jung The intensity of the mammary circulation in the goat during lactation—Gaston Julia The structure of multiple convex areas—Radu Badescu Certain uniform transcendental functions represented by series of rational functions—Jean Pierre Robert The generalisations of a singular integral equation of H. Lebesgue—Lars Ahlfors A generalisation of Picard's theorem—Henri Poincaré Elliptic cavitations—A Guerbulsky Recording the deformations and vibrations of the wing of an aeroplane in flight—A Danjon The apparent displacement of the stars in the neighbourhood of the eclipsed sun. A discussion of the observed results compared with those predicted by the theory of generalised relativity—Ernest Esclangon Remarks on the preceding paper. The deviation observed is the result of an extrapolation, and the question cannot be regarded as definitely settled without many additional observations—L Brillouin The statistics and magnetism of the free electrons—Paul Le Rolland and Tchang Te Lou A new electrical method for the determination of the dew point, applicable to thermal machines. The method is based on the fact that when water vapour is condensed on the surface of an insulator, the latter becomes conducting. The change in the resistance of the surface can be arranged to produce a sound in a telephone or to illuminate a neon tube—M Pauthenier and Mme M Moreau-Hanot The study of the motion of a heavy sphere in an ionised electric field—L Néel The magnetic susceptibility of iron some degrees above the Curie point—Felix Esclangon The realisation of monochromatic sources of red and yellow light. With tubes without electrodes containing mercury, sodium, or cadmium, the high frequency discharge takes place at temperatures of  $80^\circ\text{C}$ ,  $250^\circ\text{C}$ , and  $260^\circ\text{C}$  respectively. If some argon (pressure of the order of 0.1 mm) is introduced into these tubes, mercury lights up at the room temperature, sodium at  $180^\circ\text{C}$ , and cadmium at  $200^\circ\text{C}$ . These facts can be applied to simplify the production of monochromatic light—J P Mathieu The optical properties of 1,4-naphthalene-bisimino-camphor—Constantin Salceanu The

variation with the temperature of the magnetic double refraction of some aromatic compounds in the fused state—Mme. Irène Curie and F Joliot The emission of protons of high velocity by substances containing hydrogen under the influence of very penetrating  $\gamma$ -rays—M Haissinsky The electrolytic deposit of polonium in an alkaline medium—Desmaroux and Mathieu The structure of nitrocellulose films—Henri Muraour A theory of explosive reactions—Jean Challansonnet The constitution, spontaneous graphitisation, and thermal hysteresis of low carbon cast iron containing titanium. Silicon and titanium modify the characters of cast iron in the same direction. Both favour the formation of graphite on solidifying and on annealing. They also reduce the thermal hysteresis of the change ( $\alpha$ -iron  $\rightarrow$  C)  $\rightarrow \text{Fe} + \text{Fe}_3\text{C}$ —M and Mme Leclère The separation of the thiophene hydrocarbons contained in oils with high sulphur. A method of controlled sulphonation followed by hydrolysis of the thiophene sulphonic acids was found to be the best method of separation.—R Lespieau Study of a method of preparation of true acetylenic primary alcohols. Description of the properties of the alcohol  $\text{HC} \equiv \text{C} (\text{CH}_2)_2 \text{CH}_2\text{OH}$  and of some compounds derived from it—Roger Dolique The influence of some impurities on the critical temperature of the solution of phenol in water. Impurities in the phenol of the order of 0.1 per cent may cause differences of  $0.2^\circ$ – $0.66^\circ\text{C}$  in the critical solution temperature—Houllier The formation of travertine and peat in the Somme valley—H Arsandouy The morphological evolution of the dome of Mt Pelée—Francis Ruellan The transversal deformations in the relief of the Japanese Archipelago—Henri Coupin Loss of sexuality by a fungus—Bogdan Varitchak Nuclear evolution in *Pericystis apis*—Obaton Mantol as food for *Sterigmatocystis nigra*—D Montet The action of weak radioactivity on the germination of seeds. Black oxide of uranium was used as the radioactive material. Each kind of seed showed an effect, with an optimum varying with the nature of the seed and its surface—A Perrier Researches on the fermentation of coffee. From the results of experiments detailed it is concluded that the fermentation of coffee is not essential for the preparation of a fine product. On the contrary, if the fermentation is prolonged there is a prejudicial effect on the colour and aroma. Hence the fermentation of coffee is on a different footing from cocoa and tobacco, where the fermentation would appear to be indispensable—N Liatsikas The presence of brown steppe soils in the plain of Thessaly—A Demolon and Mlle J Brigando The fixation of proteins by the soil—Louis Fage The seasonal vertical migration in the Mysidaceae—Mlle M Gex Remarks on the neutralisation curves of biological systems, and of sera in particular—R Legroux and Kemal Djemil Transmissible lysis—A Trillat Attempts at vaccination through the air (chicken cholera)—Jean Regnier, Robert David, and Mme Alice Kaplan Contribution to the numerical study of microbial multiplication. The existence of the latent phase—C Levaditi, J Bardet, A Tchakirian, and A Vaisman The therapeutic properties of indium in trypanosomases and in experimental syphilis. Indium resembles gallium in its active therapeutic action in certain trypanosomases and experimental syphilis. Its preventive and curative activity is satisfactory in the infection produced in mice by *Trypanosoma Evansi*, but is uncertain in the treponemosis of the rabbit (*Treponema pallidum*).

## ROME

Royal National Academy of the Lincei Communications received during the vacation, 1931—G A Crocco Aerothermodynamic bodies—N Parravano

and V Caglioti Alloys of zinc and manganese X-ray investigation of these alloys reveals the existence of  $\gamma$ ,  $\epsilon$ , and  $\eta$  phases with structural characteristics analogous to those of the brasses The hexagonal  $\epsilon$  phase is stable at ordinary temperature over the range 33-24 per cent of manganese, and the cubic  $\gamma$  phase, with 52 atoms in the unit cell, has a region of existence between 22.26 and 8.09 per cent of manganese and is stable at the ordinary temperature The  $\eta$  phase, composed of solid solutions of manganese (about one per cent) in zinc, is unstable and, as it ages, undergoes de-mixing with formation of a eutectic of zinc with another phase ( $\gamma'$  or  $\beta'$ ), probably cubic—P Rondoni and G Mezzadrolì Action of ultra-short electromagnetic waves on the transplantable adenocarcinoma of the rat These waves accelerate the growth of the tumours considerably—G Barba Generalised parallelism in a  $V_3$  (2)—G Krall The adiabatic invariant in the free motion of gyroscopes—A Rosenblatt The stability of laminar movements of viscous liquids (2) Exponential damping at infinity—E Oddone A contribution of seismometry to the history of the earth Seismometric evidence supports G H Darwin's hypothesis of the birth of the moon by tidal action exerted by the sun on the earth—V Ricca Raman spectrum of ammonia in solutions of different concentrations Aqueous solutions of ammonium salts exhibit no Raman line attributable to the  $\text{NH}_4$  ion, and aqueous ammonia shows a Raman spectrum identical with that furnished by liquid ammonia It may, therefore, be concluded that, in aqueous solution, ammonia exists partly as  $\text{NH}_3$  and partly as  $\text{NH}_4\text{OH}$ , the reaction  $\text{NH}_3 + \text{H}_2\text{O} \rightarrow \text{NH}_4\text{OH}$  representing an equilibrium—F De Carli Viscosity of mixtures of stannic chloride with aromatic hydrocarbons (2) At ordinary temperatures, homologues of benzene exhibit a distinct tendency to associate with stannic chloride Such associations, which are detectable only in the liquid state and are almost completely destroyed at  $30^\circ$ , behave similarly to the compounds of the same hydrocarbons with sulphur dioxide Confirmation is obtained of the view that the substituent groups of the benzene ring contribute markedly to the greater stability of the complexes formed by derivatives of aromatic hydrocarbons—V Famiani The beri-beri quotient ( $Q_b$ ) in nutrition with polished rice and autoclaved grain Experiments with the same experimental animals (pigeons) fed with polished and washed rice, or grain autoclaved either dry or moist or in presence of alkali, reveal no substantial differences in the values of the beri-beri quotient or in the symptoms observed—G Amantea and V Famiani The possibility of obtaining permanent beri-beri phenomena in the pigeon by deprivation of the  $\beta$  factor—A Baroni Solid solutions between alkali halides X-ray investigation of the system  $\text{KCl-KI}$  fails to show even partial miscibility between the two salts in the solid state The results of thermal and X-ray analysis of the systems  $\text{KCl-KBr}$  and  $\text{KBr-KI}$  confirm those of other authors and show that a metastable equilibrium is reached, true equilibrium being attained only from aqueous solutions—V Zagami The effects on albino rats of feeding with seeds of *Lathyrus sativa* L alone These seeds form an incomplete or a qualitatively deficient food for growing rats Although no nervous or motor phenomena related to those described as lathyrism were observed, the young rats displayed diminished resistance, torpor, and pronounced slowness in growth, more particularly of the genital organs and skeleton—G B Cacciamali Contortions of the Ercinian in Alpine orogeny—G Mezzadrolì and E Varetton Influence of Italian

radioactive soils on the development of silkworms Exposure of silkworms to these soils exerts a favourable action on the development of the worms, their growth being enhanced so as to increase the weight by 32-45 per cent, and the weight of the cocoons increased by 5.8 per cent—Celso Guareschi Fusion of otocysts in xenoplastic grafting between Anura and Urodela—Teodoro Perri Behaviour of optical vesicles of *Triton* grafted on to embryos of *Rana esculenta* (destructive processes and power of recovery) (2)—M Curzi Cases of pedal gangrene from *Sclerotium* observed in Italy

## Forthcoming Events

### FRIDAY, MARCH 4

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society) (Annual General Meeting), at 3—Presidential Address  
INSTITUTE OF MARINE ENGINEERS, at 6—Annual General Meeting  
GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College), at 7.30—Prof W G Fearnside The Carboniferous Rocks of Derbyshire Derwent (Lecture)—W Pulfrey On the Occurrence of Radiolarian-bearing Nodules at the Base of the Edale Shales, near Calver, N Derbyshire (In Abstract)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir Harold Hartley Michael Faraday and Electro-Chemistry

### SATURDAY, MARCH 5

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Lord Rutherford of Nelson Discovery and Properties of the Electron (2)

### MONDAY, MARCH 7

ROYAL INSTITUTION OF GREAT BRITAIN, at 5—General Meeting  
UNIVERSITY OF LEEDS, at 5.15—Prof H J Fleure Races and their Evolution (Lecture)  
UNIVERSITY COLLEGE, LONDON, at 5.30—M Jacques Maritain Quelques Aspects de la philosophie Thomiste (Lecture) (in French)  
ROYAL SOCIETY OF ARTS, at 8—A E L Chorlton Oil Engine Traction (Howard Lectures) (1)  
ROYAL GEOGRAPHICAL SOCIETY, at 8.30—Sir Douglas Mawson The B A N Z Antarctic Research Expedition, 1929-31

### TUESDAY, MARCH 8

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr L J Witts The Pathology and Treatment of Anæmia (Goulstonian Lectures) (3)  
INSTITUTE OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30—Annual General Meeting  
INSTITUTE OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 7—Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)  
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8.30—F Wokes The Importance of Ergot in Pharmacy (Lecture)

### WEDNESDAY, MARCH 9

INSTITUTE OF METALS (Annual General Meeting) (at Institution of Mechanical Engineers), at 10 A.M.—Reading and Discussion of Papers  
SCHOOL OF ORIENTAL STUDIES, at 5.15—H J Brauholtz The Craft of the African Potter (Lecture)  
UNIVERSITY COLLEGE, LONDON, at 5.30—E A Savage Recent Changes in the Classification of Books in General and Special Libraries (Lecture)  
ROYAL SOCIETY OF ARTS, at 8—Prof E P Stebbing The New Afforestation Work in the Central Plateau of France

### THURSDAY, MARCH 10

INSTITUTE OF METALS (Annual General Meeting) (at Institution of Mechanical Engineers), at 10 A.M.—Reading and Discussion of Papers

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr. C E Lakin The Borderlands of Medicine (Lumleian Lectures) (1)  
 ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Prof J. B S Haldane Heredity in Man (4)  
 CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 5 30—Prof L Ruzicka The Life and Work of Otto Wallach (Pedler Lecture)

## FRIDAY, MARCH 11

ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee), at 4—Miss C H Wedgwood Stages of Economic Development in Melanesia  
 ROYAL SOCIETY OF ARTS, at 4 30—Indian Meeting

## SATURDAY, MARCH 12

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Lord Rutherford of Nelson Discovery and Properties of the Electron (3)

## National Economy and Fundamental Research \*

THE report which is presented annually to Parliament by the Department of Scientific and Industrial Research is not only a summary of the Department's activities but also an impressive picture of the manifold ways in which scientific research is applied alike to the solution of industrial problems and to the everyday needs of society. It might be expected that, in a year of sustained industrial depression and unemployment, the financial stringency and imperative need for national economy would direct first attention to the details of the work carried out under the Department, in search of justification for the expenditure of the sums of money entrusted to the Department. It is probable, however, that the attention of most readers will be arrested in the first instance not by the summary of work but by the report of the Advisory Council, in which a masterly analysis, over the signature of Lord Rutherford, of the development of the Department and the fundamental relations of industry and scientific research is presented.

It is only when the fundamental principles which determine the influence of industry on science and of science on industry are rightly apprehended that any accurate assessment of the detailed results of the work of the Department is possible. Recent events do not encourage an easy optimism that these principles have yet received adequate recognition in the counsels of either industry or the State. On the contrary, the report of the May Committee on National Expenditure affords uncomfortable evidence that scientific research is still regarded as an expensive luxury.

The Advisory Council has set before itself, as its main endeavour, to encourage industry to look on scientific research not as a last resource but as an essential part in the business of production. While, however, this policy has substantially increased the competitive power of British industry, and while industry is more and more anxious to take advantage of applied science whether through the Department or by other means, the Advisory Council considers that the attitude towards research is still too often one of hope rather than of faith.

The fundamental factor of the situation, that the initial advantages which Great Britain secured through her island position, her natural resources, and the technical skill of her workers, are no

\* Department of Scientific and Industrial Research. Report for the Year 1930-31 (Cmd 3989) Pp iv+186 (London H M Stationery Office, 1931) 3s net

longer sufficient in themselves to enable our manufacturers to withstand the organised and scientific rivalry of competing countries, is now generally recognised

"Scientific Research", declares the Advisory Council, "has in the past made striking contributions to industrial research and it will make them in the future. But the nation which will enjoy the benefits of science in the day-to-day progress of its industries is the nation which habitually applies scientific method and scientific knowledge, and it is that nation which will be able to seize the more spectacular achievements of science in the industrial sphere. Scientific research cannot provide a ready-made solution of any of the present industrial difficulties, but it does point the road along which persevering effort may enable industry to find a way out of some of those difficulties."

This emphasis on the need for scientific method and research in industry is welcome, but the Advisory Council does not advise or recommend unrestricted or greatly increased expenditure on research for the solution of industrial difficulties. The view is taken that the expenditure which is defensible in the national interest depends on the extent to which industry generally is prepared to apply scientific method and advances in scientific knowledge.

This admirable statement of policy has been hailed in some quarters as a justification for restricted expenditure on research, and, significantly enough, by industries the difficulties of which are notoriously due less to economic conditions than to neglect of scientific method and research in the past. Temporary protection of these industries by imposition of a tariff can only be justified as affording them an opportunity of putting their house in order, and should be contingent upon the industry re-orientating its attitude to fundamental research with the object of accumulating a reserve of fundamental knowledge to assist in tiding over bad times and to strengthen the industry to meet independently competition from abroad.

The report from the Advisory Council is, however, emphatically a plea for more widespread education in industry as in public affairs. The full utilisation of the results of scientific research and the substitution of scientific for empirical methods can only be secured as a result of confidence in the scientific workers engaged in the study of the problems concerned and of acquaintance with the existence and value of this large body of scientific knowledge and research. Marked progress in this task of education is indicated in the report, although

the research associations themselves have found it advisable to take definite steps to bring home to their members the practical significance of the scientific conclusions which have been reached. As such educational work succeeds and extends, the Advisory Council will be committed, in the pursuit of its declared policy, to increasing expenditure on industrial research, until the progression from haphazard empirical methods to those of scientific control and direction by the use of instruments of precision in technical practice, which is characteristic of the present industrial revolution, has largely been effected. The national interest clearly demands that only the capacity and willingness of industry to apply the results of such research should limit the State expenditure thereon.

The moderation of this report is, however, equalled by the breadth of its vision, and in an important section which discusses the application of new inventions, the Advisory Council points out that new industries are not in general created by direct scientific discoveries. They can usually be traced to remote origins, and the history of the relations between invention and industrial development promises no short cut to renewed prosperity. As example of this contention the report cites the growth of the radio industry from John Henry, Clerk Maxwell, and Hertz's theories and investigations in the middle of last century. Numerous other examples have frequently been quoted in our columns in discussing the influence of creative science on industry, and recently Dr L. V. Redman, in his address on "Research as a Fixed Charge" on receiving the Grasselli medal of the Society of Chemical Industry, stressed the great length of time that is usually required to bring a piece of promising research into a profitable industry.

It is these facts which lead us to view with misgivings the decision of the Committee of the Privy Council, in curtailing the expenditure of the Department of Scientific and Industrial Research, "to concentrate available funds on the work of the most immediate practical value to industry, leaving to happier times the expansion of work of which the results could only be available at some more distant date." For all that the Committee expresses the belief that the immediate usefulness of the Department to industry will not be seriously impaired by the economies necessitated, the fact cannot be disguised that the concentration recommended is, in fact, robbing the future.

It must be admitted that the Department had a difficult task and one that it could probably only

discharge satisfactorily when the education of industry and public opinion generally as to the value of scientific method and research has become much more advanced than at present. Misgivings about the actual policy adopted are less a criticism of the Department than of the general attitude to scientific research prevalent in Great Britain.

Although scientific methods are much more widely used in almost all our industries than even a few years ago, there is not yet a general disposition to accept an adequate and sustained programme of research as a fixed charge, comparable with insurance, depreciation, obsolescence, etc., without which no industry can progress, if indeed it can survive. Science, whether in its broadest aspect or its narrow technical sense, will not occupy its proper place in industry until the industrialist is prepared not merely to admit its possibilities and accept its occasional assistance but also to incorporate it as part of his industrial practice. Such incorporation involves not merely the support of research work, whether conducted in his own laboratories or outside, or in co-operation with other firms, but also continuous contact with research in matters of interest to his industry, wherever that research is prosecuted. For the pursuit of a policy of this kind, the industrialist must maintain a competent scientific staff of his own, and see that a scientific outlook is represented not only among the subordinate staff but also in high places.

This question of scientific outlook is all-important. Amid the complexities of modern industries, industrial research can easily prove sterile through misdirection; the best results can only be attained under the direction of those in whom familiarity with scientific method and outlook is accompanied by a knowledge of the economic and industrial aspects of processes which the researches may benefit or even create. Intimate contact between manufacturing practice and the work of the laboratory is essential if industrial research is to bear its proper fruit, and the development of industrial and scientific research is a matter of leadership as well as education. This is clearly recognised by the Advisory Council, and not the least important aspect of the Department's work is the assistance given to post-graduate students and others in their training in methods of independent scientific investigation under the general supervision of the Department. This assistance is a direct contribution to the staffing of scientific, technical, and administrative positions in industry with men of the requisite ability, and it is disappointing to find that during the period

1925-30 the number of students in training who proceeded to scientific service in industry or under Government was 141 and 52 respectively, as compared with 181 and 80 in the period 1920-25. The provision of an efficient scientific personnel in industry is all-important alike for the effective direction of research and for its proper assessment as an integral part of industrial policy and development.

There are many more firms than formerly in British industry where a considered research policy and programme is an accepted part of manufacturing practice, and in many others scientific and technical methods of control have replaced the less accurate empirical methods. The evidence does not show, however, that research, and in particular fundamental research, has yet received anything like full recognition from our industries as a whole. Largely this is due to the disparity between the number of administrative posts held by scientifically trained men, whether in industry or in Government service, in Great Britain as compared with other countries. The technical factors involved in modern industry and, indeed, in general administration cannot be accurately appraised apart from technical and scientific knowledge.

While admittedly many of our research workers, particularly those engaged in academic research, might with advantage be more closely acquainted with industrial conditions, there are few scientific workers indeed who imagine that research is a panacea for all industrial ills or more than one essential factor in industrial progress. Industry's difficulties arise much more from its direction by those without the essential technical and scientific training. Under modern industrial conditions, technical and scientific training is a *sine qua non* of competent leadership, and until our industries are much more widely directed by those whose scientific training and outlook render them competent to evaluate research along with other factors involved, it is improbable that industry will display the continuous reliance upon research for its development which it is the aim of the Department to foster. Still less can we expect a satisfactory and authoritative decision regarding the prosecution and endowment of the fundamental and long-range research upon which progress finally depends, until the question is considered in council by experienced industrial leaders and national administrators who count among their qualifications a first-hand experience of scientific technique.

### Engineering History

- (1) *The Story of the Road from the Beginning down to A.D. 1931* By Prof J W Gregory Pp xii + 309 + 16 plates (London Alexander Maclehose and Co, 1931) 12s 6d
- (2) *The Quest for Power from Prehistoric Times to the Present Day* By Hugh P Vowles and Margaret W Vowles Pp xv + 354 + 88 plates (London Chapman and Hall, Ltd, 1931) 15s net

ENGINEERING history not merely tells us of some of man's greatest achievements, but also of necessity carries us back to the beginning of the human race. Primitive men had their tracks and tools, and from these by a long process of evolution have come our great highways with their streams of traffic and our power-houses with their gigantic turbines and water-wheels. Thus in both these fascinating books, one on roads and the other on power, we are taken back to prehistoric times, and then step by step brought down to modern times, with all their marvellous constructions.

Both books are unusually entertaining, both can be read with pleasure either by the expert or the general reader, and both are valuable additions to engineering literature. While, however, Prof Gregory sticks closely to his text and does not trouble us with the tools and appliances the road-makers have used, Mr and Mrs Vowles, in their anxiety to give the reader as much light on the subject as possible, have included chapters on tools, metals, coal, and oil, and even on counting, measuring, and time reckoning. The foretelling of eclipses is undoubtedly of great interest, but we would rather have learnt more of what the authors could tell us of ancient water-wheels and windmills.

It is quite evident that the writing of both these books has been a congenial task to their respective authors. (1) Through his travels abroad, Prof Gregory has had experience of roads in many parts, and the reader will especially enjoy his lively reminiscences and his numerous photographs. The earliest roads, he tells us, were mere hunting trails or game tracks. Roads proper came into existence with the search for materials and for trade, and among the most famous highways of other times were the 'amber' roads of Europe and the 'silk' roads of China. Then, too, there were the 'pituri' roads in Australia, and that astonishing road of the Incas in Peru, four thousand miles long. Paved roads were laid by the Egyptians and Carthaginians, but the Romans were the first to establish a continental system of well-built roads. These matters are all dealt with in the first part of the book.

Interesting as is Prof Gregory's account of the ancient and medieval roads, of far more immediate practical importance is the part devoted to "The Evolution of the Modern Road", with all its facts and figures. Everyone is a user of roads, everyone contributes to their upkeep, everyone grumbles if they fall into disrepair, but soon no one will remember the mud of the roads of thirty or forty years ago. Our roads to-day are costly, it is true, but the saving in discomfort, in shoe leather, in tyres, and in petrol is enormous. But whether it is the teacher intending to give a lesson on roads, a motorist wishing to know how roads are made and kept in order, or whether it is one of the thousands of local councillors in the country desirous to know something of road legislation or road finance, Prof Gregory's book meets their case.

(2) The history of power is a far more complex subject than the history of roads, and calls for an intimate knowledge of up-to-date practice, a vast amount of research, and ability to marshal facts and present them in proper sequence. The success with which Mr and Mrs Vowles have carried out their task is a tribute to the amount of thought and labour they have expended upon it. The book is an admirable result of the combined work of an engineer and a historian. We greatly regret, however, to notice that Mrs Vowles died on March 4, and thus a most valuable combination has come to an end.

The scope of the book is best seen from an enumeration of its various divisions. In the first place, the whole matter is divided into three 'books'. These books contain eight, seven, and four chapters respectively. In the first book the reader makes the acquaintance of man as a tool maker, he is given a sketch of the rise of craftsmanship and of the first control of water, there are accounts of the early structural achievements, such as the pyramids, and of the dawn of transport, and to these are added chapters on the transition to iron, on early measuring, and on engineering in Græco-Roman antiquity.

In the second book the stories of the steam engine and of the steam and hydraulic turbines are told. We meet again with Newcomen, Watt, Perkins, Porter, Edison, Parsons, De Laval, Curtis, Otto, Diesel, Akroyd Stuart, Fourneyron, Francis, and others whose names are familiar to all power engineers, and are given some interesting descriptions of modern power plants. Then in the third book come chapters on the materials of power—coal, oil, alcohol, iron, steel, and other metals—their produc-

tion and properties, and the book ends with an epilogue on "World Power and the Future"

Many of the men mentioned in the book, we fear, will mean little to others than engineers, but the work does not aim at being a biographical dictionary. Like "The Story of the Road", "The Quest for Power" has that most useful feature, a good index

### Plato and the Modern Age

*After Two Thousand Years a Dialogue between Plato and a Modern Young Man* By G. Lowes Dickinson. Pp. 213. (London: George Allen and Unwin, Ltd., 1930) 6s. net

TO what extent have the greatest thinkers of the world guided or in any way controlled its destiny, and are they likely to be more enlightened and inspired and successful now or in the future than they have been in the past? The answer will doubtless vary according to our knowledge and interpretation of history. According to Carlyle, the history of the world centres around its great men, by whom he meant primarily its great thinkers, but though these great ones in the past have undoubtedly played a leading part, as it seems to us, in shaping the course of events, it has been fairly generally acknowledged, at least by the leaders of nearly every religion, that there has been an overruling Power known under various designations, among which Fate or Destiny were the most generally recognised by the ancients. Be this as it may, and reverting to that part of our question which asks whether modern or future thinkers will be more effective, it must be admitted that the quality of modern thought, as compared with ancient, is not infrequently called in question and even deplored as greatly inferior to that of the ancients. Various reasons are assigned for this, but it may at least be urged in extenuation that existence to-day is far more complex and presents much more difficult problems to the thinker than in the olden days.

The extraordinary increase in scientific knowledge has vastly extended the realm of thought and revealed heights and depths which almost make the mind reel in contemplation of the physical universe. In the political and social spheres, largely owing to scientific discovery and invention, the most profound changes have taken place, infinite complexities have been introduced, touching among other things national and international relations, so that here too the thinker can quite easily find himself nearly if not quite out of his depth. Thus we can readily see that the fields

of thought are now infinitely vast and infinitely complex, and turning to the thinker himself we find that he, for his part, has to spend so much time merely in the acquisition of knowledge, of which a certain minimum is essential, that he has little real leisure for serious meditation on the majestic but increasingly mysterious panorama of life which now unfolds before him.

It was therefore a happy thought of Mr. Lowes Dickinson to call up Plato and see how that mighty intellect would react when confronted with the problems of modern existence. The work takes the form of a conversation between the beloved master and a very modern young man, and we can say at once that it has been exceedingly well done, as was only to be expected from such a first-grade classical scholar as the author is universally acknowledged to be. The book is highly stimulative, in some parts helpful and suggestive, and occasionally provocative, thus conforming with most of the demands an eager and inquiring mind can make on any book.

If no very serious contribution is made to the solution of modern problems, it must be remembered that even a Plato, suddenly awakened after two thousand years and confronted with such a marvellously changed world, could scarcely be expected to produce, at short notice and after an hour or two's talk with a modern young man, reasoned solutions to present-day enigmas. But in the course of the talk he is often brilliantly suggestive, and at the finish he rises to transcendental heights and seems to show, though somewhat vaguely, a path upwards in which the human mind may walk with hope and faith that good will ultimately prevail, and some is even now glimmering down from a higher world to which men must strive to attain.

The subjects dealt with in the early stages of the discourse relate to property, forms of government, socialism, population control, war, and education. These comprise Part I. In the second part we have a supremely interesting discussion touching the subordination of the individual by the State in such a way that nobody was, in fact, pursuing any real good. The possibility is considered of enabling the mass of the citizens to attain a real good rather than that this privilege should be limited to a favoured few, but this is ultimately discarded as impracticable, and we next have a description of those things which may be regarded as real goods in themselves, as distinguished from means to other goods. In the final analysis real good consists in truth, art, love. The book ends

with the Platonic doctrine of immortality and of another life deeper and more significant, from which even now some light occasionally shines down

It would seem that, despite the profound and far-reaching changes in the modern world as compared with the ancient, the essential mysteries of existence are very much the same to the modern as to the ancient philosopher. We may have advanced tremendously in physical knowledge, in social organisation, and in industrial efficiency, but despite all this we are no nearer to any adequate explanation of those baffling mysteries which have always loomed up as an impenetrable curtain of the blackest darkness before the human mind.

Those of us who still cling tenaciously, though only as it were by a thread, to some remnant of religious faith, who endeavour to discern a gleam of light in that darkness, and try our hardest to believe, with Plato, that there is a good and that it will ultimately prevail, have yet to acknowledge the harsh realities of existence, and carry on with as much faith and courage and dauntless cheer as we can summon or invoke to our aid. Mr Lowes Dickinson seems to conclude on the right note, and the lofty faith of Plato prevails over the mournful scepticism of the modern young man.

W G LINN CASS

### South African Grasses

*An Introduction to the Study of the South African Grasses with Notes on their Structure, Distribution, Cultivation, etc.* By Dr E P Phillips (South African Agricultural Series, Vol 6) Pp 224 + 121 plates (Johannesburg Central News Agency, Ltd, 1931) 25s net

IT is perhaps not a mere coincidence that the two most recent works of any size on the Gramineæ have come from South Africa. In 1929, Prof Bews issued his book, "The World's Grasses", and now Dr Phillips has written on the grasses of South Africa. The study of the Gramineæ in a country where vast stretches of veld are devoted entirely to the raising of stock is of more than mere academic interest. We in Britain, who are accustomed to the lush meadows of our own land, where the cultivation of grasses presents no real difficulty, often fail to realise the troubles confronting the South African agriculturist, who has to contend with the dual effect of a poor, often alkaline soil and a low atmospheric humidity. It is not surprising, therefore, that a great deal of experimental work is being carried out by the agricultural institutions of

South Africa upon problems connected with grass-lands.

Dr Phillips has endeavoured to produce a general survey of South African grasses. In the introduction, exception is taken to Dr Stapf's use of the term 'floret', which was merely a convenient expression to include with the flower the associated bract and bracteole. All agrostologists, however, will not agree with Dr Phillips's contention that "the descriptions could be simplified, made more definite and understandable if the use of this term is discontinued."

Commencing with a survey of the principal publications dealing with the South African grasses, Dr Phillips strikes an original note in Chap. II. with a detailed list of authors and complete references to genera published by them, with the 'type' or 'standard' species of every genus. Such a comprehensive list has probably never before been compiled and should prove of great usefulness to all interested in the taxonomy of grasses.

The following chapter deals with migration and the distribution of grasses, in which the author, on the assumption that the temperate genera are more primitive than the tropical, and that South Africa enjoyed at one time a cooler climate than at present, suggests three main lines of migration: first, the migration northwards of the temperate grasses along the mountain ranges, secondly, a movement southwards of tropical genera along the valleys, and lastly, a westward migration of tropical grasses into the north-western area and the Karroo.

The questions of veld-burning, grazing, and cultivation are dealt with in another chapter, and stress is laid on the disastrous effects of overstocking, particularly of important watersheds, where the whole aspect of an area may be changed in a few years. A useful list of common names of South African grasses is also given—though, as is usual with 'common' names, the same name is frequently given to widely different plants.

A little more than half the book is devoted to the systematic side of the subject. There are keys to the grass tribes and to the genera, and a description and figure of almost every genus. For some reason, Dr Phillips has preferred to adopt Hackel's arrangement of the tribes of 1890, rather than the more modern systems of Stapf and others. This has meant the retention of the Tristegineæ, an unnatural group which has been dropped by later workers and which did not even figure in the "Flora Capensis." Hackel's Zoysieæ also is placed in the Panicoideæ, whereas all recent authors

place the Zoysieæ in the Pooideæ. At the same time, the Oryzeæ appear in the Panicoideæ, although they occupy a more natural place in the Pooideæ. There appears to have been no justification for resuscitating Hackel's system at this stage, the more so since the other works on the Gramineæ available to the South African student, such as the "Flora Capensis", "Flora of Tropical Africa", and Bews' "The World's Grasses", adopt more natural arrangements.

The key to the genera is of the dichotomous variety. It covers 29 pages and appears to work reasonably well. The descriptions of the genera are in most cases very complete, and the distribution and altitudinal range of each genus is given in almost every instance. The illustrations, however, which are line drawings—and might, quite well, have contributed greatly to the value of the book—are very poor and reflect little credit on the artist responsible. Quite a useful feature in most of the illustrations is a cross-section of the leaf—often a useful character in confirming a determination.

The book is a volume of an agricultural series, and lacks a little in quality of paper and of binding. The high price is due, no doubt, to the large number of illustrations and to the restricted circulation such a work must inevitably enjoy. The book must obviously find a place on the bookshelves of all who study South African grasslands. F B

### Short Reviews

*The Bushman*. By E J Dunn. Pp xii + 130 + 34 plates. (London: Charles Griffin and Co., Ltd., 1931.) 15s net.

THE author of this book tells us that his information was obtained by personal observation some fifty to sixty years ago while doing government geological work, chiefly in the districts bordering the Orange River. As a record of personal investigation among a people now practically exterminated, the work is of considerable value. Moreover, the writer is a geologist, and is therefore used to descriptive work and the careful noting of details.

It must be admitted, however, that the work is of unequal value. The latest books on the pre-history of South Africa, which in the nature of the case include studies of early Bushman cultures, do not seem to have been consulted. There is a large number of plates depicting stone implements, most of which would to-day be classed as belonging to the Smithfield culture, nothing is said of Wilton varieties. Admittedly, what would now be called Fauresmith types are shown as pre-Bushman on Plate xxxii, and those of the Still Bay culture on Plate xxxiii, though nothing is said about the older, Stellenbosch, implements, and no attempt is made to classify the various industries.

Similar comments apply to the art. Actually, the Bushman paintings and engravings vary in different geographical areas. For example, the engravings seem to centre around Kimberley, whereas the finest paintings are found in the mountains to the east, another series of paintings totally differing in style can be seen in the extreme south and south-east of the Union. Mention of superpositions of paintings, giving a chronological sequence, is made but not followed up. As a matter of fact, results of recent work on the superpositions of styles over large areas seem to suggest that most of the art in Southern Rhodesia is much earlier than that of the Union, and that it is these Rhodesian paintings which so resemble those of late Palæolithic age in eastern Spain. Incidentally, too, the African paintings are not really like those of the French and North Spanish group, such as can be seen at Altamira, with which the author compares them.

Yet after this somewhat drastic criticism, I should like to say again that records of first-hand observations of Bushmen, made at a time when they still flourished, are not easy to obtain to-day, and the memories of an observer with a scientific mind are therefore very valuable. M C B

*Publications of the Wagner Free Institute of Science*  
Vol 2 *Studies of Evolution in the Genus Spirifer*  
By C L Fenton. Pp x + 436 (50 plates). (Philadelphia: Wagner Free Institute of Science, 1931.) 6 dollars net.

THE work of a palæontologist who applies experimental biological principles to his results, and by their aid formulates a theory of evolution, is bound to be of general interest. The author has studied the evolution of three genera of spirifers, *Sp. varians*, *Sp. obliquistratus*, and *Sp. hungerfordi*, in minute detail, and finds that none of the existing theories of evolution will account for the apparent orthogenetic tendencies of characters such as ornament, which cannot be of selective value. Natural selection, heterogenesis, Buffonism, Lamarckism, Eimer's theory of orthogenesis, and Guyer's serologic orthogenesis are all found to be insufficient or unsatisfactory.

The theory of racial life cycles is made the basis for a new theory of phyletic senescence through decreasing metabolism. Child has found that the metabolic rate is high in a young cell or organism, and that there is a general decline throughout normal life. Mr Fenton applies this principle to the racial cycle as well as to the life cycle, and states that racial senescence is due to a similar falling off in the metabolic rate. Evidence of such racial senescence is shown by a "general progressive increase in susceptibility to injury and other disturbance, and a decrease in the capacity for repair". The whole hypothesis is based on a physiologicoheredity—that is, variations initiated physiologically are impressed on the germ plasm.

In proposing a theory which requires so close a connexion between ontogeny and phylogeny, the author states he finds that ontogeny recapitulates phylogeny in general in the spirifers, but the ontogenetic record of phylogeny may be distorted by

tachygenesis and lipopalingenesis. The Biogenetic Law is generally supported by palaeontologists. This, he explains, is because in animals with shells, such as brachiopods and molluscs, the early stages form a permanent and not a temporary basis for new characters as in insects or vertebrates, usually selected by those who criticise the Biogenetic Law. Thus new characters arise by additions to the life cycles and not by modifications of pre-existing characters.

*Пегматиты их научное и практическое значение*  
Tom 1 *гранитные пегматиты. (Pegmatite Eigenschaften, Geochemie, Verbreitung, Verwendung Band 1 Granitpegmatite)* By A. E. Fersmann. Pp. 646. (Leningrad Akademie Nauk SSSR, 1931.) 20 rub.

THE author has devoted more than twenty years to the study of pegmatite, personally explored many of the pegmatite areas in Russia and abroad, and initiated organised investigations of the problem in Russia centred in the Mineralogical Museum of the Russian Academy of Sciences. The book sets down, in a monographic form, the main results of theses and studies, and reviews critically the work of other authors. In the first part (Chapters 1-x) a general discussion of the chemical, physical, morphological, and geological characters of pegmatites is presented, and the methods of investigations are described. The second part (Chapters xi-xviii) contains a monographic description of various pegmatites and their classification. The following chapters (xix-xxv) constitute the third part, containing a discussion on the mineralogy of pegmatites and on the geochemical and metamorphic phenomena connected with their origin. A bibliography of the main literature on pegmatites and a list of pegmatite areas of Russia are appended, while a special appendix is devoted to the economically important pegmatites. A second volume, dealing specially with the pegmatites of the basic, sienitic, and nephelin-sienitic magmas, is in the course of preparation.

*The Reclamation of Land from the Sea*. By F. M. Du-Plat-Taylor. Pp. xv+153. (London: Constable and Co., Ltd., 1931.) 21s net.

LAND reclamation and coast erosion are matters which very closely concern the inhabitants of sea-bordered countries. The Dutch have for centuries waged an unremitting contest with the sea, driving it back inch by inch, in order to provide themselves with space to live and expand. Not less vital in Great Britain to the dwellers of East Anglia and Yorkshire is the gradual but constant encroachment of the sea on their clay cliffs and erodible soils, and though, as Sir George Courthope points out in his introductory note, "England has gained from the sea more than she has lost", the local losses are not always, or necessarily, compensated by the gains elsewhere.

Major Du-Plat-Taylor's book commences with an exposition of the objects and methods of reclamation, and proceeds to consider in detail systems of reclamation by enclosure, with a special

account of the project for the reclamation of the Zuyder Zee (to which two chapters are allocated). Reclamation by filling and by simple drainage are also considered. There are chapters on the auxiliary works and plant required for the various operations of reclamation and drainage work, embodying a good deal of useful information, a certain amount of which has been derived from the author's personal experience. Altogether, the book will be of undoubted utility to practising engineers, as assembling a quantity of data and information for reference in a compact and accessible form. There are numerous illustrations, both views of works and diagrams. B. C.

*Jahrbuch des Forschungs-Instituts der Allgemeinen Elektrizitäts-Gesellschaft* Band 2, 1930. Pp. 332. (Berlin: Julius Springer, 1931.) n.p.

THE second annual volume of the Research Institute of the Allgemeine Elektrizitäts-Gesellschaft maintains the high standard of scientific and technical achievement reached in the first volume. It is beautifully printed on art paper, and so the photographs are excellently reproduced. All the economic and technical papers given have previously appeared in various trade journals, but the scientific worker will find most of them of great interest. Advanced mathematical theorems are given fairly fully, so that it is not difficult to verify them, and the mathematical symbols are clearly printed. The papers are collected into groups under definite headings, for example, acoustics, electro-optics, electron physics, atomic physics, atomic chemistry, electric heating, etc. The various sections are connected by prefatory reviews giving a résumé of the present state of the research field.

Scientific workers will be interested in the 'demonstration research' into Störmer's polar light theory by E. Brüche and W. Ende, and in the paper on "Theoretical and Experimental Results on the Aurora Polaris", by E. Brüche. The latter paper is printed in English. To illustrate the thoroughness with which the technical researches are carried out, we find in a paper on electric cooking the specific heats of many articles of diet. The specific heat of milk is given as 0.90, oysters 0.84, eggs 0.76, veal 0.70, fresh fish 0.80, fruit 0.81, game 0.80, pork 0.55, pork fat 0.50, blood 0.93, and so on.

*The American Annual of Photography, 1932*. Vol. 46. Edited by Frank R. Fraprie. Pp. 294 + Ads. 46. (Boston, Mass.: American Photographic Publishing Co., London: Sands, Hunter and Co., Ltd., 1932.) Paper, 10s.; cloth, 15s.

THIS photographic annual is exceptionally well produced. It contains many examples of modern work. The book is mainly devoted to articles on photographic topics, a few of these are technical, but for the most part they deal with the artistic side of the subject. A few pages at the end of the book are devoted to a "Formulary" in which are brought together a great many formulæ for developers and such like necessities. S. O. R.

## The British Polar Year Expedition, 1932-33

ON the ground that the relatively meagre scientific results from previous polar expeditions were due to their sporadic occurrence, Lieut Weyprecht, of Austria, proposed in 1875 that an effort should be made to organise a number of simultaneous expeditions which would co-operate on a uniform plan over a full year. The result was the organisation of what has come to be called the First International Polar Year, 1882-83, when fourteen expeditions were sent out by twelve different countries, twelve to high northern latitudes and two to the Antarctic. Great Britain collaborated with Canada in establishing a station at Fort Rae, on the north arm of the Great Slave Lake. All the stations were fully equipped with such instruments as were then available for comprehensive meteorological and magnetic observations, they worked on a common pre-arranged plan. Judged from the practical results and the large number of researches that have been based on the data collected during that First Polar Year, the venture was entirely successful.

Since 1882, progress in meteorology, terrestrial magnetism, and allied lines of investigation has developed apace, and many problems dependent for their solution on a repetition of just such a co-operative network of stations as set up in the First Polar Year, but using improved and more refined methods of recording and observation, have presented themselves. It was felt that there could be no more fitting celebration of the jubilee of the first international year than by repeating it, and in 1929, on a proposal of Admiral Dominik of the Deutsche Seewarte, the International Meteorological Conference undertook to organise a Second Polar Year. The International Union of Geodesy and Geophysics, at its meeting at Stockholm in the same year, endorsed the proposal and promised financial aid. An International Commission for the Polar Year, 1932-33, was set up, with Dr la Cour of the Danish Meteorological Service, as president. National committees were appointed in each country to organise the several contributions in these countries in collaboration with the International Commission.

In Britain the National Polar Year Committee, with Sir Henry Lyons as chairman, represents the interests of the Royal Societies of London and Edinburgh, as well as most of the other societies and institutions interested in such work. The Government, through the Meteorological Office, Air Ministry, has promised a grant-in-aid not exceeding £10,000 to the Polar Year efforts in Great Britain, and this has been supplemented by many generous donations in instrumental and food equipment by British manufacturers and wholesale firms.

Because it was strongly recommended by the International Commission that, so far as possible, the original Polar Year stations should be re-occupied, the British National Committee decided to send a party to the Fort Rae site on the Great Slave Lake. [Canada this year will organise her

own Polar Year programme: the main station will be established at Chesterfield Inlet, with probably a second at Copper Mine for photographic auroral work.] The reopening of the mountain observatory on Ben Nevis was also considered, but questions of cost and doubts as to the real value to be obtained from only a year's further observations led to that part of the programme being dropped. Efforts were to be concentrated in equipping very fully the Canadian station at Fort Rae, and to reinforcing the observational facilities at key stations in the British Isles for meteorological and auroral work. At a later stage it was decided that advantage should be taken of opportunities for getting a complete survey of the variations in the magnetic field at high latitudes, and also auroral observations and photographs from the same stations, to establish a station for measurements of the ionisation content and its variations in the conducting regions of the upper atmosphere. It has now been decided that Prof E V Appleton will take a fully equipped party to Tromsø this summer for such work, and the party will continue to observe throughout most of the Polar Year period.

The programme of observational activities drawn up by the International Polar Year Commission is concerned almost wholly with meteorology, terrestrial magnetism, aurora, and, to a less extent, atmospheric electricity. In each of these subjects the equipment of the British party to Fort Rae will be complete. In addition to maintaining continuous records of all the meteorological elements by autographic instruments, much attention will be given to the investigation of the conditions in the lower levels of the atmosphere by observational and instrumental methods. Frequent pilot balloon ascents will give an insight into the circulation over that part of north-west Canada, and special efforts will be directed to penetrating the stratosphere by sounding balloons on certain days each month previously selected by the International Commission. To obtain the most useful information about the temperature conditions up to and, if possible, well beyond the tropopause will necessitate the sounding balloon with its attached self-recording meteorograph ascending to 12 km at least. The recovery of the instrument bearing the record after the apparatus has fallen in the difficult country around the Lake is one of the problems connected with the expedition not yet solved.

For the work in terrestrial magnetism the expedition will be equipped with alternative sets of absolute instruments, a Smith portable magnetometer and earth inductor representing the modern methods, and a Kew unifilar magnetometer and a dip circle representing the older technique. For the continuously recording instruments the intention is to take three complete sets of magnetographs, each independently capable of recording by photographic means the variations in the three components of the earth's field. Of these, two sets have been specially designed for high latitude

work by Dr. la Cour, Copenhagen, and will supply the standard and special quick-run traces respectively. By running a third set of variometers at low sensitivity it is hoped to ensure that even in the biggest perturbations of the field during magnetic disturbance no trace will be lost. The provision of a double set of absolute instruments is intended not to cater for emergencies alone, the present Fort Rae, which will be the main base of the expedition, is some seventeen miles farther up the north arm of the Great Slave Lake than the settlement of fifty years ago. For such purposes as establishing the secular change in the magnetic elements it will therefore be necessary to carry out sets of parallel observations at this subsidiary station.

The necessity for occasional occupation of the old Fort Rae site will be turned to further useful account by equipping the sledge party which will travel there in the winter months with a spare auroral camera, and by having some means of communication between the two bases. In this way it is hoped to use the two posts as base line stations for photography of aurora, and so to provide data for determining its height by the well-known methods developed by Prof Stormer. It is of interest to observe in this connexion that, so far as is known, Fort Rae is very near to the zone of maximum frequency of aurora.

These three fields of meteorology, terrestrial magnetism, and aurora constitute the primary work of all the Polar Year stations, but, in addition, the party at Fort Rae hopes to obtain very complete information regarding the atmospheric electrical

and allied phenomena of the region. Using a Bennet electrograph, continuous records of the potential gradient of the earth's electric field will be kept, and equipment will be taken to observe, whenever opportunity allows, the conductivity of the air and the air-earth current using a modified Wilson electrometer, the small ion content of the air using a modified Ebert apparatus, the nucleus content with the standard Aitken instrument, and, if possible, the rate of production of atmospheric ionisation with an apparatus specially designed at Kew Observatory.

The Fort Rae party will consist of six men under the leadership of Mr J M Stagg of the Meteorological Office. They will leave England about the middle of May of this year and proceed via Montreal to Edmonton. North of Edmonton the route will lie down the River Athabasca to the lake of that name, and then down the Slave River, past the seventeen miles of rapids between Fitzgerald and Fort Smith, to Fort Resolution on the south side of the Great Slave Lake, thence across the body of the lake and up the north arm nearly to its most northern extremity. This should be reached by the third week in June, thus giving time to erect the special non-magnetic huts required for the absolute observations and continuous registration of the magnetic field and instal the instrumental equipment in readiness for the official starting date of the Second Polar Year on Aug 1. The party will continue observing until as late in August 1933 as may be safely done without undue risk of being frozen in for the next winter.

### The Drumm Traction Battery

By Prof A J ALLMAND, F R S

WIDE interest has recently been aroused by reports of the successful trials of an electric tram propelled by a Drumm transport battery, as also by certain details concerning the battery itself which have been made public. During the last two years I have had ample opportunity of examining and experimenting with the Drumm cell at various stages of its evolution, and it seems desirable now to put on record a statement of its main electrochemical features.

It is an alkaline cell, and the only metals which enter into its construction are stainless steel, pure nickel, and, at present, nickelled steel. Its mechanical strength and so forth are correspondingly satisfactory. As in other successful alkaline batteries, the positive plate system consists of the  $\text{Ni}(\text{OH})_2$  -  $\text{Ni}(\text{OH})_3$  mixture first developed by Edison, several types of such positives have been employed. Whereas, however, in other cells, the negative plate system is essentially  $\text{Fe}$  -  $\text{Fe}(\text{OH})_2$ , it consists of  $\text{Zn}$  -  $\text{Zn}(\text{OH})_2$  in the Drumm battery. Moreover,  $\text{Zn}(\text{OH})_2$  is soluble in alkali, whilst  $\text{Fe}(\text{OH})_2$  is not. Consequently, instead of containing a solid hydroxide which becomes reduced to metal on charge, the Drumm negatives consist of nickel gauze grids, immersed in the solution of zinc oxide in potash

constituting the electrolyte, and these on charge become coated with metallic zinc. The cell reactions in this 'zinc' accumulator, written in their simplest form, are consequently

as compared with

in the 'iron' accumulator.

One feature of such a cell will be immediately obvious. Owing to the relative positions of zinc and of iron in the electrochemical series, its voltage will be unusually high for an alkaline cell. Depending somewhat on the part of the positive discharge curve used in practice, the average figure under normal conditions for the fully charged cell is about 1.86 volts, as compared with about 1.34 volts for the iron accumulator. The forty per cent increase represents a considerable advance. This is important, but the main advantage claimed by the inventor, which would seem to put the cell in a class of its own amongst transport batteries, depends on facts of quite a different nature.

Briefly, whilst the two electrode processes  $\text{Fe} + 2\text{H}^+ \rightleftharpoons \text{Fe} + \text{H}_2$  are subject to considerable irreversible effects, which limit the maximum practicable current densities to relatively low figures, this is not the case with the electrode processes  $\text{Zn} + 2\text{H}^+ \rightleftharpoons \text{Zn} + \text{H}_2$ . There is no need to emphasise a point known to all. Iron is a metal which becomes passive with notorious ease when used as anode, and the work of Foerster has demonstrated the existence of important retardation effects during its cathodic deposition. Zinc, on the other hand, dissolves freely on anodic polarisation, as in many types of primary cell, and very high current densities are known to be used successfully in its technical electro-deposition. As a result, far heavier currents can be put through a Zn/Zn than through a Fe/Fe electrode, during both charge and discharge. The properties of the  $\text{NiO}/\text{Ni}_2\text{O}_3$  electrode are sufficiently good from the same point of view with the consequence that the Drumm battery, which combines these two electrode systems, can both be charged and discharged at abnormally high rates. The standard rate of charging of a single technical cell of total weight 112 lb, allowing for all losses in efficiency, corresponds to an input of 0.134 effective watt-hour/lb/minute, about four times the rate normal to other alkaline batteries. In practice, the same cell is normally discharged at a current of 400 amperes and an average voltage of 1.65 volts, equivalent to practically 0.1 watt-hour/lb/minute. This itself is twice the highest discharge rate recommended for other alkaline batteries. But, over and above this, the current can, when required, be raised to 1000 amperes for limited periods, corresponding to an energy delivery of about 0.22 watt-hour/lb/minute—a very high figure indeed. The cell deals with these heavy loads quite comfortably, with no sign of deterioration.

The power of furnishing energy at these unprecedented rates makes it possible for a traction battery of Drumm cells to overcome the grave disadvantage inherent in the majority of such batteries, namely, the impossibility of furnishing rapid accelerations. The train now operating between Dublin and Bray can accelerate from a standstill at about 1 mile per hour per second, attain speeds of 40-50 miles an hour with ease, and is provided with a successful system of regenerative braking, whereby an important fraction of the energy surge made available on a down-gradient or on decelerating at a station is returned to the battery.

There is one further very important matter. The

specific watt-hour capacity of the Drumm cell on a single charge is not particularly high. In fact, in the case of the battery especially designed for the above train, it is very low—perhaps 15 per cent of that of an iron battery. But its capacity for high loads enables this battery to be charged at the terminus and afterwards discharged many times during the working day, probably twenty such charges will be standard when in full operation. Consequently, the daily work of which unit weight of battery is capable will be, not 15 per cent, but 300 per cent of the normal—a fact naturally of prime importance when considering initial costs, quite apart from the elimination of the expense of an all-night charge.

With regard to other practical points, the cell possesses to a high degree the virtues of simplicity of construction and of operation, whilst there are definite grounds, which I am not at liberty to mention, for anticipating a long life. Neither overcharge, nor overdischarge, nor long idle periods have any ill effect of importance. Self-discharge is exceedingly low.

A few electro-chemical details may be added in conclusion. Under standard working conditions, the average current efficiency is 92-93 per cent, the concordant result of long-continued tests on cells of varying capacity. The average voltage during charge and discharge is 2.03 and 1.65 respectively. The energy efficiency is therefore practically 75 per cent. These are favourable figures, and strikingly so when it is remembered for what high loads they hold good, they also connote relatively small gassing and low temperature rise. During the greater part of both charge and discharge periods, the polarisation alters linearly with time. Investigation shows this change to be due almost entirely to the positive plate. The polarisation at the negative is considerably less than at the positive, and scarcely alters with time (unless the cell be overdischarged). Of the total voltage losses in a cycle, roughly half is associated with the positive, and one-quarter each with the negative and the electrolyte. The exact concentrations of caustic potash and of zinc oxide in the latter vary in accordance with the purpose for which the cell is designed, and there is no point in giving detailed figures. The essential points are, of course, an electrolyte of high conductivity and sufficient dissolved zinc oxide for the operating conditions.

It is clear that Dr. Drumm has produced a cell of somewhat remarkable properties, and that, although primarily designed for transport purposes, these properties may lead to its utilisation in other fields.

### Adsorption of Gases

THE recent discussion held by the Faraday Society at Oxford, on Jan 12-13, was devoted to a consideration of the problems connected with the adsorption of gases. The general introduction was given by Prof. H. S. Taylor of Princeton University, and a number of distinguished foreign guests presented their communications in person, including Prof. A. Magnus of Frankfurt, Prof. A. F. Benton of Virginia, Prof. E. Huckel of

Stuttgart, Dr. A. Farkas of Frankfurt, and Drs. H. Dohse and Schuster of Ludwigshafen. The attention of the meeting was devoted almost exclusively to two important considerations, types of adsorption and discontinuities in adsorption processes.

A study of the chemical behaviour of adsorbed molecules as well as the great difference in the heats of adsorption of gases on substances such as silica

and the metals led to an early differentiation between two types of adsorption, one where the adsorbate was relatively lightly attached, with small heats of adsorption, and another type where the heats of adsorption approximate to those involved in chemical linkages. These were early characterised as physical and chemical adsorption respectively. If this is in fact the case, it should be possible to demonstrate the actual existence of these two types of adsorption in the same system, for the physical type which is only loosely held should be operative alone at low temperatures, whilst the other type should occur at higher temperatures, if as in chemical reactions an energy of activation is required. Examples of such dual adsorption processes in the same system were first demonstrated by Benton and later by Nikitin, more recently their number has been extended very considerably by Taylor, by Garner, and by Kingman.

Following the earlier concepts, it has been customary to consider the low temperature adsorption as due to Van der Waals forces, and the one occurring at higher temperatures and requiring an energy of activation as due to chemical forces, that is, due to a change in the character of the union of the metal to adsorbate. An analysis of the problem by Lennard-Jones indicates that this is not necessarily the case, for a diatomic molecule may be regarded as dissociated on activation into atoms on the metal surface, and it is shown that the potential curves for the approach of a molecule and of an atom may cut one another, so that the transition from one form to the other is possible. In the non-activated adsorption we are dealing with the system  $M + X_2$ , in the activated adsorption with  $M + 2X$ , the nature of the forces involved in both cases are, however, identical. It is clearly possible that, in addition to non-activated and activated adsorption, chemi-adsorption involving a more fundamental electronic change may occur, for example,  $M + X \rightarrow M^+X^-$ , requiring again a different energy of activation. Examples of all three types of adsorption are known, and the evidence for the presence of these three types in one system over a suitably wide range of temperature has been presented by Garner.

Activated adsorption probably cannot involve in all cases the actual separation of the atoms in a diatomic molecule into two independent entities, for example, carbon monoxide on metals, nor can the energies of activated adsorption and of chemi-adsorption be always widely different from one another, for it appears probable that oxygen on most metals, and nitrogen on many metals, undergoes chemi-adsorption as readily as or more readily than activated adsorption. It is interesting to note that the activated adsorption of carbon dioxide on iron probably involves the formation of carbon monoxide, which is 'physically' adsorbed, and chemi-adsorbed oxygen. It is also worthy of comment that the linkage of the metal atom holding the adsorbate is weakened by the process of chemi-adsorption, and in many cases on re-evaporation the substrate is removed in true chemical combination with the adsorbate.

The nature of the process of activation is as yet not so clearly visualised. Adopting for energies of activation values less than 15,000 calories per gm. molecule, activation cannot result on mere collision of a gas molecule with any portion of the metal surface, since the velocity of the process at low temperatures is too small. Certain portions of the surface appear more susceptible than others. The investigations of London and of Polanyi make it appear probable that the energy of activation is dependent on the lattice spacing or the distance between two metallic atoms in the adsorbent. The energy required for activation rises rapidly as a certain optimum spacing is departed from either on contraction or expansion.

Over certain ranges of temperature the rate of uptake of gas in the activated adsorbed state is slow. No unanimity of opinion was obtained at Oxford as to the cause of this slow rate of uptake. It is believed by some that this actually represents the rate of activation, and energies of activation have been calculated from the velocities at different temperatures. That the process of surface migration and intergranular diffusion along the secondary structure of the metal crystal on solid surfaces requires an energy of activation for the adsorbate to jump over the potential barriers between the atoms has been experimentally demonstrated in a number of cases, and formed the subject of several communications, including those of Becker for alkali metals, Volmer for mercury and benzophenone, Charlton, Semenov and Shalnikov for metals, Ward for activated adsorbed hydrogen on copper, and by the writer for gases. As pointed out by Lennard-Jones and by Fowler, this is in accord with the general theory, energies of activation for migration of adsorbed, activated adsorbed, and chemi-adsorbed molecules being in general necessary and of different magnitudes.

The increase in rate of activated adsorption with the temperature and the energy of activation calculated therefrom must be ascribed either to an increase in the number of doublets formed by thermal agitation of the metal or alternatively to an increased rate of diffusion of the activated adsorbed molecules (in some cases possibly as atoms) away from the doublets. Both factors may indeed be operative over certain ranges of temperature. That activated adsorbed gas can actually leave the seat of activation and migrate over the substrate was evident from the communication of Frumkin and of Egerton and Ubbelohde, and a distinction between the two hypotheses is also possible by an examination of the effects of poisons on the process, as exemplified by the work of Maxted.

Whilst the pressure retention curves both for adsorption and activated adsorption over considerable ranges of pressure and temperatures obey the isotherm of Langmuir, examples of change of state of the adsorbed gas or vapour, as exemplified by the interesting work of Farkas and Bonhoeffer on the para-ortho hydrogen inversion on nickel surfaces, are by no means uncommon, for example,

cæsium on tungsten, examined by Langmuir. Even more remarkable, however, are the minor discontinuities or steps observed by Allmand, Burrage and Chaplin for the adsorption of vapours such as carbon tetrachloride and sulphur dioxide on charcoal and on silica gel, and by Benton and White for hydrogen at low temperatures on metals and nitrogen on copper and iron.

The phenomenon appears to occur with normal adsorption rather than with activated or chemisorption, and is ascribed by Benton to prefer-

ential adsorption on various selected portions of the substrate, such as the edges and corners of the micro-crystals of the metal.

It is probable that many of the visitors to this large and well-organised meeting came with the idea that only one type of adsorption was certain, but it is almost inconceivable that they left Oxford without being conversant with at least three types of adsorption, the characteristics of which could easily be recognised but the nomenclature of which remained undetermined. ERIC K. RIDEAL

### Obituary

SIR WILLIAM SOMERVILLE, K B E, LL D.

ALTHOUGH illness led to his retirement from active work some years ago, the sudden death from pneumonia, on Feb. 17, of Sir William Somerville, emeritus professor of agriculture and rural economy in the University of Oxford, came as a shock to many friends. To the progress made by agricultural education during the past fifty years his contribution was outstanding. Those who knew Somerville only in the committee room or common room, even those who recognised in him a delightful companion in the open air, equally at home in the field and woodland and garden, happy with a gun under his arm, but, above all, content with a rod in his hand and a meerscham pipe between his lips, must sometimes have asked themselves how it was that among practical farmers his reputation was unrivalled, and why among foresters his opinions on arboricultural questions were so highly valued. Other notices of him have dealt with his later career; here reference will be made chiefly to his early work in the years when he acquired the experience which made him in later life so valued a counsellor.

Somerville had attended the agricultural class at the University of Edinburgh when John Wilson was professor, but I do not think that he then had any intention of taking up agricultural education as a career. When Robert Wallace moved from Cirencester to succeed Wilson at Edinburgh in 1885, Somerville, attracted by the energy and reputation of the young professor, resumed his interrupted studies; he was class medallist in Wallace's first year, and when he had graduated at Edinburgh and at Munich, I believe it was the influence of Wallace that led him to adopt teaching as a profession. He considered the offer of an appointment in India in 1889, but for family reasons he then decided not to leave Edinburgh, and being specially interested in forestry, which he had studied in Munich, Somerville began his career as lecturer in forestry in his own University.

In 1891, Somerville went from Edinburgh to Newcastle-upon-Tyne as professor of agriculture and forestry in the Durham College of Science (now Armstrong College). Reference to his work there is made below. In 1899 he was elected Drapers' professor of agriculture at Cambridge. He was the first occupant of this chair, and the two years which he spent in Cambridge were devoted to the organisation of the new department, the provision of a farm

for experimental work, and to establishing contact with farmers in the eastern counties. In 1901 he left Cambridge on being appointed an assistant secretary in the Board of Agriculture and Fisheries, but the multifarious duties which tie an assistant secretary to a Whitehall desk were little to the taste of a man with Somerville's love for the field and woodland, and in 1906, when an opportunity of returning to educational work presented itself, he accepted the Sibthorpian professorship at Oxford, and there the rest of his working life was spent.

When he settled in Oxford, Somerville had two objectives. In his official capacity it was his duty to develop there a course of study suited to the needs of the Oxford student. It was clear that the special circumstances of those likely to inherit land or to undertake estate-management must be kept in view, and to them Somerville was specially fitted to act as friend and guide. But Somerville's ideals were not satisfied by lecturing on principles. He held it to be his duty to practise as well as to teach; he therefore acquired and farmed land in two English counties. He had had much experience in experimental work, but here his object was demonstration, not experiment—his farms were run on commercial lines. He knew that he could make farming pay, and he did.

Somerville's concentration on teaching and demonstration in his later years gave rise to an impression that his interests lay chiefly in practical farming, and that by nature he was not an experimenter who loved his work for its own sake. This was not the case. In his early years Somerville was an enthusiastic and indefatigable experimenter. He was not prepared to take statements on trust. His motto, indeed, was 'Prove all things', and he followed up this injunction by holding fast to what he found to be good. In public discussion, once his point of view had been stated he was very difficult to move; he always had facts ready if his views were challenged. But Somerville was by no means dogmatic; he would weigh deliberately points put to him in conversation, and was as ready to agree as to differ. His attitude when his views were challenged in public, those who knew his early work can explain and can justify.

When Somerville went to Newcastle in 1891, his knowledge of the subjects then interesting Scottish farmers and his German training in scientific methods enabled him both to grasp quickly those

questions on which farmers in the north of England required exact information and to devise field experiments of a kind likely to give the information needed. He was as active as he was methodical. He sought out farmers, got permission to use their land, and enlisted their interest so fully that most of the cost of the experimental work carried on was borne by them. The result was that in a belt of country between the Solway Firth and the North Sea numerous local stations were established and hundreds of experimental plots laid down. The purpose was strictly experimental, the sites selected were not intended for demonstration, for at the time it was not known how crops would respond to the special treatment. Some of these field stations were used for demonstrating results, but this use came at a later stage.

The range of Somerville's field experiments was wide. In the early years the crops of arable land and meadow hay were prominent subjects, the work on pastures with which his name was afterwards identified began in 1896. Most of the local experiments related to the effects of manures, but other subjects such as the prevention of finger-and-toe in turnips, lucerne inoculation, and a study of the productiveness of important pasture plants occupied his attention.

After the acquisition of Cockle Park Farm by the Northumberland County Council in 1896, experiments on arable land were extended to a group of miniature farms, permanent meadow plots were laid down, experiments in cattle and sheep breeding were initiated, a series of experimental plantations, including the chief forest trees, was formed, and the well-known work in 'Tree Field' was begun. Animals (in this case sheep) were used to measure the changes brought about in pastures by different fertilisers, for Somerville then realised, as does the biochemist to-day, that the apparatus and reagents of the laboratory may fail to detect subtle differences in the food of animals.

Somerville was a keen observer, he kept careful notes, he used the weighbridge wherever its use was applicable, and he accumulated a mass of data on which his reports were based. By 1899, when he left the north of England, he had published eight reports on his work. These reports extended to more than 800 octavo pages, they contained many thousands of figures and much discussion of experimental results.

Somerville not only worked hard, but he worked also in favourable circumstances. His district provided a wide range of soil types and several markedly different climates. These were just the conditions likely to supply hints for further experimental studies to a pioneer investigator. This was not all. It was his good fortune to work among observant and intelligent men, holding very definite opinions acquired as the result of their own experience, but men not unwilling to learn if satisfied that their instructor's knowledge, like their own, had been acquired at first-hand. Lectures were not greatly appreciated, but discussions were enjoyed, and might be protracted.

Somerville took a deep interest in his pupils, and

this interest was shared by his gifted wife, in term time they kept open house, and any Sunday visitor would find a gathering of students there. Nor did interest end when undergraduate days ceased, former pupils were frequent visitors. Pupils and Oxford colleagues combined to present him with his portrait in 1924. Thereby they earned the enduring gratitude of Somerville's friends, for the man himself stands out in Mr Hall Neale's picture. The stalwart build, the familiar pose, the well-coloured meerschaum, the twinkle in the eyes—they are there, and any visitor to Oxford may see what manner of man William Somerville was. Linking the skilled practice of the nineteenth century with the new knowledge of the twentieth, he commanded the confidence of farmers and foresters, the respect of his pupils, and the affection of his friends.

THOMAS H. MIDDLETON

#### SIR FREDERICK ANDREWES, O B E , F R S

F. W. ANDREWES was born at Reading in 1859. He was educated there and at Oxford, where, from Christ Church, he took a first class in the final honour school of natural science in 1881. He was afterwards Burdett-Coutts scholar and held the Sheppard medical fellowship at Pembroke. In 1882 he went to the Royal Hospital of St Bartholomew with an open scholarship to pursue his medical studies, and remained in intimate association with that institution for the rest of his life.

At first Andrewes dabbled with practical medicine and was at one time in professional charge of the nursing staff at Bart's and an assistant physician at the Royal Free Hospital. But after Kanthack was translated to Cambridge in 1897, he settled down to pathology, and for thirty years was head of that department and in due course a professor in the University of London. He retired in 1927, though he went on with his own laboratory work until a few months ago. In the summer of 1931 he had a desperate illness while on a visit to New York, from which he made a remarkable recovery, but he died from an extension of the disease on Feb 24. He was elected F R S in 1915 and knighted in 1920.

Andrewes' interests were always clinical and he looked on pathology as something which promoted good medical and surgical practice. He was little concerned with general and academical problems. In this field he was extraordinarily successful, primarily at his own hospital and indirectly elsewhere, in drawing the laboratory and clinical practice together and showing his medical colleagues by actual experience that bacteriology could be a great deal more useful to them than they had supposed.

In those days this was more difficult than it is now, and Andrewes owed much of his success to his sympathy and personality and his capacity for seeing points of view other than his own. Many of his assistants and colleagues in the pathological department were clinicians, and one of the pieces of work for which he is best known is his investigation with T. J. Horder of the streptococci pathogenic for

man Their classification was put forward in 1906 and has formed the working basis of innumerable subsequent inquiries, it is only in the last few years that further progress has shown that their criteria of differentiation are not wholly adequate in the systematisation of a difficult group

Throughout his career Andrewes was so constantly adding here and there to bacteriological knowledge that it is difficult to pick out particular pieces of work and it would be tedious to enumerate them all During the War, he became interested in the serological analysis of dysentery and typhoid-like organisms, and in 1922 made an important contribution to what has since proved to be a singularly fertile field In morbid anatomy he published little one recalls his definition of the histological characteristics of Hodgkin's disease in 1911 and a chemico-anatomical study of degenerate arteries in 1912

Andrewes was one of the few pathologists of his day who could write and talk with clarity and distinction it was always a pleasure to read or listen

to him Amiable and witty, he was universally popular, and he will be very much missed His son, Dr C H Andrewes, has already made his mark as a member of the research staff of the Medical Research Council

We regret to announce the following deaths

Mr Andrew A Blair, formerly chief chemist of the United States Geological Survey, known for his work in the chemical analysis of iron and steel ores and alloys, on Jan 25, aged eighty-three years

Prof E H Griffiths, F R S, honorary fellow of Sidney Sussex College, Cambridge, formerly principal and professor of experimental philosophy in the University College of South Wales, on March 3, aged eighty years

Mr H Chapman Jones, formerly for many years senior demonstrator in chemistry in the Royal College of Science, London, on March 7, aged seventy-seven years

### News and Views

#### Royal Society's Selected Fellows

THE following seventeen candidates have been recommended by the Council for election to the Royal Society Prof F C Bartlett, professor of experimental psychology in the University of Cambridge, Prof Davidson Black, professor of anatomy in the Union Medical College, Peking, and honorary director of the Cenozoic Laboratory of the Geological Survey of China, Dr F W Carter, consulting engineer to the British Thomson-Houston Co, Ltd, Rugby, Prof W G Fearnside, Sorby professor of geology and dean of the Faculty of Science in the University of Sheffield; Prof. F. E. Fritsch, professor of botany in the University of London (East London College), Prof J A Gray, Chown research professor of physics in Queen's University, Kingston, Ontario, Prof J B S Haldane, Sir William Dunn reader in biochemistry in the University of Cambridge, head of the Genetical Department, John Innes Horticultural Institution, and Fullerman professor of physiology, Royal Institution; Prof D R Hartree, Beyer professor of applied mathematics in the University of Manchester, Dr K Jordan, director of the Zoological Museum, Tring, Prof F R Miller, professor of physiology, Faculty of Medicine, University of Western Ontario; Sir Basil Mott, Bt, past president of the Institution of Civil Engineers; Dr J B. Orr, director of the Rowett Research Institute, Aberdeen, Prof J L. Simonsen, professor of chemistry in the University College of North Wales, Bangor, and formerly professor of organic chemistry, Indian Institute of Science, Bangalore, Mr T Smith, head of Optics Section, National Physical Laboratory, Prof H S Taylor, professor of physical chemistry and chairman of the Department of Chemistry, Princeton University, U.S.A., Prof H. W. Turnbull, professor of mathematics in the University of St Andrews, Prof Warrington Yorke, professor of tropical medicine at the Liverpool School of Tropical Medicine, University of Liverpool.

#### Royal Society of Edinburgh Elections

AMONG the fellows elected into the Royal Society of Edinburgh at a meeting held on March 7 were the following associated with scientific work E C Barton-Wright, chief assistant to the Scottish Society for Research in Plant Breeding, Edinburgh, Major S L Bhatia, professor of physiology and Dean, Grant College, Bombay, Prof J C Brash, Department of Anatomy, University of Edinburgh; Prof E P Cathcart, Department of Physiology, University of Glasgow, Prof. V. Gordon Childe, Department of Prehistoric Archaeology, University of Edinburgh; Dr. David Clouston, formerly agricultural adviser to the Government of India and director of the Imperial Agricultural Research Institute, Pusa, Prof L S P. Davidson, Department of Medicine, University of Aberdeen, Prof A Murray Drennan, Department of Pathology, University of Edinburgh, Prof Andrew Hunter, Department of Biochemistry, University of Glasgow, J. B. Lockhart, mathematical master of Edinburgh Academy and honorary treasurer of the Edinburgh Mathematical Society, A G MacGregor, geologist, H M Geological Survey (Scotland), Prof. J J R Macleod, Department of Physiology, University of Aberdeen, Prof Charles McNeil, Department of Child Life and Health, University of Edinburgh, J M Murray, divisional officer, Forestry Commission, Edinburgh, M Y Orr, botanist in government service, Edinburgh, Dr J N. Pickard, research worker in genetics and physiology, University of Edinburgh, Dr G Prasad, reader in mathematics, University of Allahabad, Prof. T Slater Price, Department of Chemistry, Heriot-Watt College, Edinburgh, Dr John Pringle, senior geologist, acting palaeontologist, Geological Survey (Scotland); Dr J M Robson, research worker, Institute of Animal Genetics, University of Edinburgh; A R Barbour Simpson, senior geography master, Cranford School, Wimborne, Dorset, J. B Simpson, geologist, H M.

Geological Survey (Scotland), Dr J-B O Sneed, lecturer on heat engines, Royal Technical College, Glasgow, Dr W E Swinton, curator of fossil reptiles and amphibia, British Museum (Natural History), Henry Wade, senior lecturer in clinical surgery, University of Edinburgh

#### Royal Horticultural Society

THE unveiling of a plaque commemorating the foundation of the Horticultural Society in 1804 (designated 'Royal' in 1861, during the presidency of the Prince Consort), the initial proceedings of which were conducted in a room at Messrs Hatchards, booksellers, Piccadilly, London, was the occasion of a representative gathering on March 7 at the firm's establishment, which is on the site of the older house. It is claimed that London annals do not provide any precedent recording in this way the foundation of a society having scientific relationships. The plaque has been placed on the face of the building in Piccadilly, whilst an illuminated record, inscribed with the names of the original promoters, is placed inside. These were The Right Hon Charles Greville, Sir Joseph Banks, John Wedgwood, R. A Salisbury, W T. Aiton, William Forsyth, and James Dickson. The unveiling ceremony was performed by the Hon Henry McLaren, president of the Society, and Mr Gerald Loder, past president.

At the original meeting of the Horticultural Society in 1804, John Wedgwood (1766-1844) was chairman. He was the eldest son of the illustrious Josiah Wedgwood, and was strongly attached to horticulture, notwithstanding the limitations of the period. An early paper of his dealt with the propagation of dahlias. Some proposals that Wedgwood drew up, accompanied by useful notes, were largely instrumental in bringing the Society into being. He had observed the rise of societies for the improvement of agriculture—the British Mineralogical Society of that time was actively engaged in examining specimens of earths or soils to aid the science of husbandry—but no organisation existed for the sole purpose of encouraging horticulture. Hence, the object of the newly formed Society was the collection of information respecting the culture and treatment, culinary as well as ornamental, of plants and trees, and the publication of papers on horticultural subjects. From modest beginnings, the Society has now achieved a membership of 27,000.

#### Faraday's Work in Electrochemistry

The subject of Sir Harold Hartley's Friday evening discourse at the Royal Institution on March 4 was "Michael Faraday and Electrochemistry". From 1832 until 1834 Faraday was mainly occupied with electrochemical researches. He first showed that amounts of electricity which produced the same effect on a galvanometer also liberated the same amount of iodine when passed through a solution of potassium iodide. He then went on to systematic investigation of the amounts of different elements which are liberated when the same current is passed through a series of solutions or fused substances, and established the two fundamental laws of electrolysis which still stand

as the quantitative basis of electrochemistry. He investigated also the mechanism by which a current passes through an electrolyte, and his ideas were crystallised in the nomenclature which he devised with the help of Whewell. All his new names—ion, anion, cation, electrode, and electrolysis—we use to-day with the significance which Faraday gave to them. In addition, he explored the source of the energy of the voltaic cell and forecast its relation to the affinity of the chemical reaction taking place in the cell. With the help of extracts from Faraday's diary, Sir Harold traced the development of Faraday's electrochemical work, repeating the decisive experiments which were the milestones of its progress. Faraday's electrochemical researches rank among the highest of his achievements. They were carried out in a short space of time with amazing economy of effort—it took him only two days to establish a connexion between the quantity of electricity and the amount of chemical action due to it—thanks to the combination in Faraday of brilliant imagination, unerring instinct for essentials, and unrivalled mastery of experimental technique, and his main conclusions still hold good to-day.

#### The Aryans

SIR ARTHUR KEITH's Frazer lecture on "The Aryan Theory as it stands To-day", which was delivered in the University of Glasgow on March 4, was lacking neither in courage nor in imagination. Much water has passed under the bridge since Max Muller was accused of confusing race and language. Sir Arthur, holding that race and language are two aspects of one problem, nevertheless admits that for clearness we should have one name for the languages of Europe and another for its peoples, namely 'Caucasian'. From a reconsideration of the problem in the light of the evidence which has accrued recently from Ur, Kish, and Susa, and a survey of the distribution of racial types in early times, he derives the Caucasians from the plateau extending from Mesopotamia to India, for which he suggests the name 'Gedrosian'. In rejecting Europe as the place of origin of the Aryan tongues and practically reverting to the area west of the Pamirs put forward by Max Muller, Sir Arthur relies on the evidence of prehistory that down to somewhere about 3000 B.C. the culture of Europe was of too rudimentary a type and its inhabitants too few to make it probable that migration was to, rather than from, the highly organised agricultural communities of the east. It will be seen that Sir Arthur gave his hearers much material for careful pondering, his views implying a frank acceptance of racial and linguistic anomalies difficult to explain on any theory. He went further and asked of the Aryan theory that it should explain the triple racial zone of Europe and the diffusion of the Aryan tongues.

#### Forecast and Fact in Science

THE fourteenth annual Earl Grey Memorial lecture of Armstrong College (University of Durham) was given on March 3 by Dr R. A. Sampson, Astronomer

Royal for Scotland, on "Forecast and Fact as seen by an Astronomer". Dr Sampson began by showing how man has transformed the world by his intellect, pointing out that such discoveries as those of Michael Faraday will live for ever, while the work of man's hands will crumble away. The world is growing more and more dependent upon science, and the changes brought about by science are for the good of humanity. Yet man cannot become superior to Nature. Nature is complicated, and the physicist is apt to go too far when he views it as something precise when it is really something vast, the mysteries of which can only be guessed. Forecast in science is, therefore, like a shot fired at an unseen target, the starting-point is clear, but afterwards we enter into unknown country, and next to nothing is really known of remote epochs in the future. Many great prophecies, such as the 'heat death' theory, representative of what has been put forth in the name of mathematical certainty, are only of value scientifically if they are certain; but as science advances and ideas change, are they certain? A distinction should be made between the immediate applications of science and the wider claims that are sometimes made for it, and scientific forecast should be taken with a grain of the salt of common sense. Scientific workers, however, realise that all they really know is due to men like Faraday and Einstein, who do not think of practical results. The theoretical mind is the soul of science—the prophetic soul dreaming of things to come; but one should read any scientific forecast as one would read an imaginative poem.

#### Institute of Chemistry

At the fifty-fourth annual general meeting of the Institute of Chemistry, held on March 1, the president, Dr G. C. Clayton, presented the Meldola Medal, the gift of the Society of Maccabæans, to Dr G. F. Marrian, of University College, London, in recognition of his researches on vitamins and hormones. In moving the adoption of the Report of the Council, Dr Clayton said that the roll of fellows and associates of the Institute now exceeds six thousand. The proposal to petition for a supplemental Royal charter, with the view of securing for members the use of the title "Chartered Chemist", has been postponed. The examinations arranged by the Board of Education and the Institute jointly for National Certificates in Chemistry are proving of real value in co-ordinating and raising the standard of chemical training in technical colleges. Referring to the separate publication of various lectures, including Sir Frank Smith's Gluckstein memorial lecture on "Chemistry and the Community", Dr Clayton emphasised Sir Frank Smith's view that, even in these difficult times, chemical research must be continued. New problems are awaiting solution, and many which have been solved are yet to be developed on the large scale. Chemical industry is an excellent barometer for indicating the outlook in industry generally, because it supplies some of the materials required for so many industries, and signs of a change for the better are

not lacking. The Appointments Register Committee of the Institute reports that about 190 (or rather more than 3 per cent) of the members are without appointments, the number of unemployed qualified professional chemists in Germany is 1500 out of about 10,000 (15 per cent). Dr G. C. Clayton was re-elected president of the Institute.

#### Education in Public Schools

THE headmaster of Eton gave a very interesting and suggestive address, which has recently been printed, on "The Education of the Average Man", at the Royal Institution on Dec 18. His humour and open-mindedness, and his wide and special knowledge of the public schoolboy, command a sympathetic hearing for his views; and with the general tenor of them most people will agree. He deploras the constriction caused by the examination system, thinks the boys are called upon for a sort of all-round specialism which it is impossible to achieve and is calculated mainly to engender a distaste for further learning, and would himself lay stress on three great aims—accuracy, curiosity, and observation. He speaks frankly as the spokesman of the public schools, which he describes as lying between the upper and nether millstones of the preparatory schools and the university examiners. In all of this there is much sound criticism and good sense; but one is bound to recognise the limitations of Dr Alington's point of view. He is almost entirely critical, except of these public schools which are to him the one virtuous element struggling with adversity, and he is also almost entirely *laudator temporis acti*, the older system, as he himself knew it, seems almost always preferable.

WITH all possible sympathy and thanks, one must put one or two larger questions than Dr Alington has raised. Is he really content with the ideal that the education of the élite of the young men of Great Britain should go on indefinitely on the lines of a simple bifurcation of 'sides' as between classics and mathematics, which is what he seems to imply? The classics boy, which is what he was himself, is not to be bothered with the algebra which he cannot understand, and is to have some general or recreative lessons or lectures on science, literature, and history. Would he not agree that with improved methods far more might be done without distaste or overloading, and, in particular, that a modicum of mathematics is desirable for the average boy, this modicum to include an introduction to the calculus? As to history and literature we are inclined to agree with him that they are not suitable subjects for examination, certainly not for the present type of examination. But as to the scope of the history taught we should go much further than he suggests. History and the historical spirit are in fact the new element in human thought, which is bound to become, we will not say dominant, but reconciling, in the increasing complexity of the curriculum. Through that alone we may hope to gain some harmony and a simplification of the mass of knowledge we have to face.

### Association of Technical Institutions

THE annual general meeting of the Association of Technical Institutions was held in the Leathersellers' Hall, London, on Feb. 26-27. Sir John Dewrance was elected president for the year 1932. Among the papers read to the meeting were "Technical Education and the Bakery Trade", by W. H. Quinn of the Leeds Technical College, "Technical Education in Canada", by Prof. R. W. Angus of the University of Toronto, and "The Teaching of Modern Languages in Technical Colleges", by P. G. Wilson of the City of London College. Each of these papers contained special points of interest to those who govern and administer technical colleges, as well to those who seek, at this kind of conference, specialist information. It is possible, however, that interest in papers (which have already been printed and placed in the hands of those attending some days before the conference) is considerably lessened when they are again read exactly from their text. There is a procedure vaguely called 'speaking to the paper'; it may not always be the happiest procedure, but it has the merit of allowing the writers of the papers to bring out succinctly matters which are afterwards the points round which debates may swing.

PROBABLY the *pièce de résistance* of the meeting was the report on "Policy in Technical Education". It had been drawn up by a Joint Committee of the Association of Technical Institutions and the Association of Principals of Technical Institutions. It was accepted, and will doubtless be discussed further by other interested bodies. Indeed, the charge was made at the meeting that an earlier consultation might have been made with bodies representing local education authorities. Whether that charge could be sustained or not, however, the recommendations are such as might be strengthened by help from other interested bodies. They do not present what might be called new ideas for the better conduct of technical education. Indeed, the majority of them have already been passed in resolution form by at least one other body, and have received publicity in our own columns and those of other, more purely educational, journals. But their present grouping will do much to help their translation into practice. In particular we welcome the recommendations urging administration of technical colleges on a regional basis (industry does not organise itself in local units), closer co-operation with universities, increase of full-time senior day technical courses, the extended provision of junior technical schools as an alternative form of secondary education (including arrangements for transfer at appropriate ages from one form of secondary education to another), the development of the teaching of industrial economics, and of facilities for physical training and social activities.

THE first part of the work undertaken by the Commission on Educational and Cultural Films—the preparation of a report on the use of the cinematograph in the service of education and social progress—is now drawing to a close. The report is in progress of com-

pletion, and will be considered at a full meeting of the Commission in April. The researches of the Commission have been far-reaching, and the conclusions deal not only with the advantages to be derived from cinematography within the narrow limits of scholastic education, but also with its cultural influence in the public cinema. The emphasis laid at successive meetings of the Imperial Conference on the assistance which motion pictures can give to the stimulation of Imperial trade and scientific research, combined with the investigations of the Colonial Office into their use among native races of the Empire for educational, medical, and agricultural instruction, present cinematography in a new light as a bond of unity in the British Commonwealth of Nations. A study of the organisation of film institutes in foreign countries leads to the consideration of the possibility of a similar national institution which will apply constructive ideas to cinematography both in Great Britain and throughout the Empire. The Commission has been impressed by the need for a central organisation capable of distributing information concerning the use of motion pictures in all departments of activity. If provision can be made for the Commission to continue its work for a while, it is proposed to take as the main object the preparation, in conjunction with educational associations, of a catalogue of films approved for use in teaching and in research.

### Gallium, a Commercial Product

WITH reference to the paragraph in NATURE of Feb. 27 (p. 309) on the commercial production of metallic gallium at a moderate cost by the Vereinigte Chemische Fabriken at Leopoldshall, Stassfurt, it was stated that the price ruling about twelve months ago for the commercial metal was about 175 gold marks per gram. This price was quoted from the *Chemiker-Zeitung*. Messrs. Adam Hilger, Ltd., inform us that they have been able to supply, not the commercial metal, but highly purified gallium, since October 1925, together with a spectrographic report upon the residual impurities in it, at prices ranging between £5 10s. and £6 10s. per gram. The chief impurity contained in this material is indium (0.8 per cent), though slight traces of lead and silver were also found. Messrs. Hilger also state that they are now in a position to supply, at £5 5s. per gram, together with a still more detailed spectrographic report, a product of even greater purity, which has been extracted electrolytically from the oxide in the research laboratories of the Sir John Cass Technical Institute, London.

### Species Hybridisation in Animals

A BOOK on species hybridisation in animals is very badly needed, but would involve much labour in its compilation, as, although there is a good deal of information on the subject available, it is very much scattered. A notable and well-illustrated contribution is that of Mr. R. I. Pocock in the *Field* for Jan. 30, on captive-bred hybrids between the lion and the tiger, apropos of the recent death of the well-known specimen at the London Zoological Gardens. This animal was bred in India between a tiger and a lioness, and

resembled a lioness with stripes; these were very faint. A mane was present, but so poorly developed that it could be rivalled by the frill of some tigers. Mr Pocock, on the other hand, has met with a specimen in which the colour was so rich that it resembled rather a stripeless tiger, and it may be mentioned that others have been bred in which the stripes, though not so strong as in the pure tiger, are quite noticeable, one such is figured, as well as the Zoological Gardens specimen, but not mentioned in the text. These hybrids appear to be always sterile, and because of this, and because of the lesser distance between the parent species, are less interesting than the hybrids between the male polar and female brown bear which were bred in Germany before the War. These were fertile, at any rate with the polar bear, one of the three-quarter-bred animals was like the latter, with a brownish back, a first cross being brown with a white polar-bear-shaped head; both were on view at the London Zoological Gardens.

#### 'Bullying' amongst Birds

IN *Cage Birds* for Jan 23, p 62, R E D Barrington records a curious case in which a female siskin, which had been persistently bullying a male before a blue-fronted Amazon parrot, was, after careful inspection, pulled through the bars of the cage and killed by the latter after it had been released from its own. This disposition to interfere in the quarrels even of alien species in what we should call the cause of justice appears to be widely spread in birds, judging from occasional instances which the writer has witnessed. A gannet thus interfered between two greater black-backed gulls, striking one which had injured and was pursuing the other, a female ruddy sheldrake forced a male common sheldrake to drop a mallard duckling which he was holding up by the tail, a piping crow-shrike (*Gymnorhina*) habitually attacked a magpie when it was bullying some other bird of the crow tribe, jay or jackdaw, and ultimately, it was said, killed it. These were captive birds, but Indian house-crows at large attacked a kite which was plucking alive a dabchick, not by the usual stealthy manoeuvres with which they often try to rob this bird of its food, but by a fierce direct assault, which seemed to suggest a sympathy one would certainly not have expected in crows. He has seen no similar instance in mammals, but Romanes, in "Animal Intelligence", records what seems like one, when a very sensitive terrier would seize his sleeve if, when driving, he touched the horse with the whip, in evident deprecation.

#### Archæological Expedition to the West Indies

It is announced by the Smithsonian Institution that, in pursuance of the plan for a systematic anthropological and zoological survey of the West Indies, Mr Herbert W Krieger, a curator of ethnology of the Institution, is proceeding to the little-visited San Salvador and Cat Islands of the Bahamas as a 'one-man expedition' of archæological investigation. The specific object of the expedition is to identify the "naked, painted Indians, with fine high foreheads" who were the first inhabitants of the New World to be encountered by Christopher Columbus. It is by

no means certain which island was the scene of Columbus's first landing; though San Salvador would appear to have the best claim. The record of the appearance of the Indians affords little clue to their identity, but Mr Krieger is of the opinion that the fact that several of these islanders served Columbus as interpreters along the coast of Cuba, up to a point to the west where their language was no longer understood, suggests that they may have been of the Arawak stock. It is known that the inhabitants of the Cuban coast were Arawak. It is possible, however, that they may be entirely unrelated. Mr Krieger's previous investigations in the West Indies have revealed evidence that the Arawak were preceded by a race of primitive non-agricultural people who lived in caves, and of whom rumours appear in the writings of the early Spanish chroniclers. Mr. Krieger will follow up his investigations in the Bahamas by an examination of the shell-heaps of central Cuba, which previously has not been explored archæologically.

#### Hydroelectric Power in Southern Scotland

THE central area of Scotland will soon be largely supplied with electric power by three water power companies. Two of them, the Grampians Electricity Supply Company and the Lanarkshire Hydro-Electric Power Company, are already operating, but it will be three or four years' time before the Galloway Water Power Company will be in a position to supply. The Galloway Company will shortly begin to build five water power stations, of a total capacity of 102,000 kilowatts, extending from the neighbourhood of Loch Doon in Ayrshire to Tongland near Kirkeudbright. Four of these stations depend for their power on the falling level of the River Ken, the lower part of which is the Dee. The other station, Glenlee, gets its power from a large artificial reservoir to be formed by a concrete dam on the Black Water of Dee between Newton Stewart and New Galloway. It will store the run-off water from an area of about forty-nine square miles. The scheme provides for a dam across Loch Doon which will raise its level twenty-three feet. At present Loch Doon discharges itself by the River Doon into the Firth of Clyde. In future the main portion of its water, with the exception of the compensation water which the company must continue to supply to the River Doon, will be diverted into the River Ken. Thus it will flow into the Solway Firth. When this is done, the water in the Doon, made famous by Burns, will be very appreciably less in bulk, but its flow will be more uniform than at present. The greatest of the water power stations is at Tongland on the Dee, about  $1\frac{1}{2}$  miles above Kirkeudbright. A dam is to be built across the gorge, giving a fall of just over a hundred feet. The level of Loch Ken is to be raised several feet, so as to give additional storage for Tongland.

#### Proposed Ship Canal in France

THE ambitious project of a ship canal across southern France has lately been revived and is receiving some attention. In *Terre, Air, Mer* for February a few details of the scheme are given. The proposal is that the

canal should start at the port of Bordeaux, follow the River Garonne to Toulouse and then the course of the railways to Narbonne, and open into the Mediterranean at La Nouvelle, about twelve miles to the south. The course would be approximately that of the present barge canal that crosses from Atlantic to Mediterranean and about 250 miles long. But the new canal would have a depth of 44 feet and a width of nearly five hundred feet at the surface and about two hundred at the bottom. There would be fourteen locks, but apart from the delay at these, vessels would be able to maintain a speed of 14 knots. The gain in distance between, say, Southampton and Port Said by the use of the canal would be about twenty-three per cent of the total mileage.

#### Announcements

SIR WILLIAM J POPE, professor of chemistry in the University of Cambridge, has been elected chairman of Council of the City and Guilds of London Institute in succession to the late Dr Morton Latham.

DR B A KEEN, assistant director of the Rothamsted Experimental Station, will deliver the G J Symons memorial lecture before the Royal Meteorological Society, on March 16, at 7.30. The subject of Dr Keen's lecture will be "Soil Physics in Relation to Meteorology".

THE sixth International Botanical Congress will be held in Amsterdam on Sept 9-14, 1935. The following executive committee has been elected: *President*, Prof F A F C Went (Utrecht), *Vice-President*, Prof J C Schoute (Groningen), *Treasurer*, Dr W C de Leeuw (Bilthoven); and *Secretary*, Dr M J. Sirks (Wageningen).

A SYMPOSIUM entitled "Is the Carbon a Failure? a Symposium on Arc Illumination and its efficiency under present conditions in Studio and Cinema", will be held at a meeting of the British Kinematograph Society at the Gaumont British Theatre, Film House, Wardour Street, on April 4, at 7.45 p.m. Anyone interested in the subject is invited to attend the meeting.

SIR GEORGE BUCKSTON BROWNE, donor of Down House and of the Royal College of Surgeons Research Farm, Kent, Sir David Thomas Chadwick, secretary of the Imperial Economic Conference, and Mr Philip Guedalla, author of "The Duke" and other works, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service.

At the annual general meeting of the Geological Society of London, held on Feb 19, the following officers were elected for this year: *President*, Sir Thomas Holland, *Vice-Presidents*, Prof E J Garwood, Mr J F N Green, Mr W Campbell Smith, Dr H H Thomas, and Prof W W Watts, *Secretaries*, Prof W T Gordon and Prof P G H Boswell, *Foreign Secretary*, Sir Arthur Smith Woodward, *Treasurer*, Mr F N Ashcroft.

THE PRINCE OF WALES will declare open Manson House, Portland Place, the new headquarters of the Royal Society of Tropical Medicine and Hygiene, on March 17, at 5.30. The Right Hon Sir Austen Chamberlain, with the president, Dr G Carmichael Low, will be present to receive the Prince. Admission will be by ticket only. A laboratory meeting will be held on the same day, at 8.15, at the Royal Army Medical College, Grosvenor Road, Millbank, by kind permission of the commandant, Colonel R B Ainsworth.

A PAMPHLET showing the provision made for professional and middle class people at voluntary hospitals in London, that is, the 'pay beds' available, has just been published for King Edward's Hospital Fund for London, by Sir Joseph Causton and Sons, Ltd, 9 Eastcheap, London, E C 3 (price 3d, post free). A useful preliminary statement describes the 'pay bed' system and the contributory schemes available in connexion with it. The 'pay beds' in London have increased from 590 in 1920 to 1577 in 1931.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A principal of the Sheffield City Training College for Teachers—The Director of Education, Education Office, Sheffield (March 14). An assistant aeronautical engineer in the Army Air Corps, Irish Free State—The Secretary of the Civil Service-Commission, 45 Upper O'Connell Street, Dublin, C 8 (March 18). An inspector for general duties and two inspectors for live-stock duties, under the Department of Agriculture for Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (March 19). A whole-time qualified research worker at the Hospital for Consumption and Diseases of the Chest, in connexion with the Halley Stewart Grant for Investigation of Tuberculosis in Children—The Secretary, Hospital for Consumption and Diseases of the Chest, Brompton, S W 3 (March 19). A clinical assistant and research student at the Cardiff City Mental Hospital—The Medical Superintendent, Cardiff City Mental Hospital, Whitechurch, Cardiff (March 21). Two whole-time veterinary inspectors under the Agricultural Committee of the East Sussex County Council—The Director of Agriculture, County Hall, Lewes (March 29). A Jenner memorial student in bacterial chemistry at the Lister Institute of Preventive Medicine—The Secretary, Lister Institute, Chelsea Bridge Road, S W 1 (April 8). An assistant lecturer in mathematics at the Royal College of Science—The Secretary, Imperial College of Science and Technology, South Kensington, S.W 7 (April 11). A geneticist and botanist at the Institute of Plant Industry, Indore, Central India—The Secretary to the Board of Governors, Institute of Plant Industry, Indore, Central India (applications from the Orient), The High Commissioner for India, India House, Aldwych, W C 2 (applications from Great Britain and overseas) (in each case June 9). A director of the National Institute for Research in Dairying, University of Reading—The Secretary, National Institute for Research in Dairying, Shinfield, near Reading.

## Oxygen and Everest

THE discussion at Section I of the British Association, following Prof J Barcroft's paper, as well as Dr. Greene's article<sup>1</sup> and the correspondence from Dr. Greene and Mr N E. Odell<sup>2</sup> which have followed, on "Oxygen and Everest", suggest that there is no accord among physiologists as to whether oxygen may be of assistance to climbers at very high altitude. In reality, Dr Greene's "oxygen school" and "no-oxygen school" do not exist at all. All physiologists agree in believing that the limiting factor of altitude is, roughly, the alveolar partial pressure of oxygen.

A few years ago Talenti<sup>3</sup> brought some people breathing 98 per cent oxygen in a steel chamber down to a pressure of 115 mm mercury, which corresponds to a utilisable oxygen pressure of 67 mm. mercury

$$\left[ (115-47) \times \frac{\%O_2}{100} \right]$$
 The limit to low barometric pressure breathing air may be fixed at about 300 mm mercury (Margaria, 1929), which corresponds to a utilisable oxygen pressure of 53 mm mercury. As people when brought to low barometric pressures showed a much higher pulmonary ventilation when they breathed air than when they breathed oxygen, so the alveolar oxygen pressure ought to have been very nearly the same in both cases. This fact alone would be sufficient to show that practically the only difficulty due to altitude is the low oxygen tension, and that when it is removed by increasing the oxygen tension in the air, the limiting altitude would be increased. In view of these facts and my results<sup>4</sup> on the working capacity of men breathing air at various barometric pressures, we had very little doubt when we tried climbing experiments in the low barometric chamber in Oxford (Barcroft, Douglas, Kendal, and Margaria)<sup>5</sup> of the success of the experiments.

These experiments showed once more, directly, that a man can work at a much lower barometric pressure than that existing on the top of Mount Everest if the utilisable oxygen pressure is kept to a sufficiently high level.

The only thing which may have raised some doubt about the utility of oxygen, climbing at high altitudes, was the report of the Everest expedition of 1924, when climbers did not get any appreciable advantage from 'breathing oxygen'. We must first criticise what 'breathing oxygen' meant in that case, and see if the experiments on Everest have been carried out with a technique good enough to justify the striking conclusions at which they arrived.

The breathing apparatus used in that Everest expedition (Odell) was 33 lb (15 kgm) weight, had a capacity of 1605 litres oxygen, and was arranged to give a delivery at continuous flow of a maximum of 2 litres per minute: the oxygen was conveyed by a rubber tube to a pipe kept between the teeth. Now assuming a utilisation of 75 per cent of the oxygen in this way, and a pulmonary ventilation of, say, at least 30 litres per minute, the percentage of oxygen in the inspired air must have been raised from 21 to 24.4, due to the extra oxygen, and the utilisable oxygen pressure from 43 mm to 50 mm mercury. So the effect of the 'breathing apparatus' was, in the most

favourable conditions, to raise the utilisable oxygen pressure only 7 mm. We can scarcely believe that this value was high enough to compensate for the greater work necessitated by a heavy apparatus, the trouble of looking after it—for it needed continuous care—and the difficulty of working with the pipe between the teeth, with an open mouth, and doing complicated movements to prevent oxygen flowing during the expiration.

In this way we can explain why in the last Everest expedition climbers did not get any advantage from the oxygen, but that is not due to the oxygen being of no value, but because the principle of the oxygen apparatus was wrong and did not increase the oxygen tension in the inspired air to an appreciable extent. Such an experiment cannot form the basis for a 'no-oxygen school'.

There is no doubt then that oxygen, if supplied in sufficient amount by a good breathing apparatus, is useful for the climber at high altitude, the experiments in the pressure chamber were carried out on subjects not acclimatised to low barometric pressure, though the climbers of Mount Everest arrive at the point of attack of the mountain already acclimatised, after weeks of walking at high altitude. The doubt of some climbers as to whether the experiments in the pressure chamber are comparable to the experiment of real climbing, owing to the difference in acclimatisation of the subjects, has not much ground, in fact there is no reason to suppose that the acclimatisation to low barometric pressure decreases the resistance to the low oxygen pressure, when pure oxygen is breathed. On the contrary, this is very probably increased by acclimatisation to high altitudes.

So there remains only what Prof Barcroft calls 'the problem of the engineer', that is, the construction of a suitable apparatus for the respiration of a rich enough oxygen mixture. The safest and simplest way would be, of course, to breathe pure oxygen from a mouthpiece or a mask. On this principle the expired air may be (a) wasted, that is, not utilised again, as we did in the chamber experiments, or (b) rebreathed after previous absorption of the carbon dioxide by soda lime.

In (a), assuming a pulmonary ventilation of 30 litres per minute at 250 mm pressure, the requirement of oxygen would be, for 5 hours climbing, 3000 litres of oxygen at 760 mm mercury, about 4.3 kgm. The transport of such an amount of oxygen would not be possible with oxygen gas because of the weight of the containers: it would only be possible with liquid oxygen, if it were possible to bring it to the highest camps and fill the specially constructed breathing apparatus with it.

As regards (b), assuming an oxygen consumption similar to that in the Oxford chamber, where the subjects made an ascent and descent of 1000 feet an hour, the amount of oxygen required would be, for a 5 hours' climb, not more than 450 litres or 0.64 kgm. To this the weight for the carbon dioxide absorber must be added, which, if it were caustic soda, would be 80 gm. for every 32 gm of oxygen, assuming a respiratory quotient of 1, assuming an efficiency of 50 per cent of the caustic soda absorber, the weight of it ought to be 3.2 kgm, making altogether about 3.8 kgm. Then the 'engineer' ought to be able to provide a suitable breathing apparatus with such amounts of oxygen and carbon dioxide absorber, which, together with the weight of the containers, does not weigh too much, say 20-25 kgm, and the breathing apparatus ought to be well tested, particularly as regard the action of cold on the functioning of the respiratory valves on the freezing of the condensed water in the tubes, etc. This could be tested on our Alps.

If it is not possible practically to use liquid oxygen or even oxygen gas because of the excessive weight of the containers oxygen could be provided by some peroxide, say sodium peroxide from the reaction  $2\text{Na}_2\text{O}_2 + 2\text{H}_2\text{O} \rightarrow 4\text{NaOH} + \text{O}_2$ , we see that we can get 1 molecule of oxygen for every 2 molecules of  $\text{Na}_2\text{O}_2$ . Then for case (a) 3000 litres of oxygen could be provided by 21 kgm of sodium peroxide, for case (b) 450 litres could be provided by 31 kgm, in this case the caustic soda resulting from the decomposition of the sodium peroxide could also be utilised for the absorption of carbon dioxide.

The relative practicability and suitability of the above methods is the 'problem of the engineer'. From the physiological point of view, the problem of reaching the top of Mount Everest is already solved within the limits of probability of biological experiments.

RODOLFO MARGARIA

Laboratorio di Fisiologia,  
Torino, Feb 2

<sup>1</sup> Greene, R., NATURE, 128, 893, Nov 28, 1931

<sup>2</sup> Odell, N. E., NATURE, 128, 1037, Dec 19, 1931

<sup>3</sup> Talenti, C., Arch. Sc. Biol., 14, 125, 1930

<sup>4</sup> Margaria, R., Arbeitsphysiologie, 2, 261, 1929

<sup>5</sup> Barcroft, Douglas, Kendal, and Margaria, Arch. Sc. Biol., 1932, in the press

MR ODELL's remarks,<sup>1</sup> regarding Dr Argyll Campbell's experiments, which were designed to test the power of acclimatisation of animals to low oxygen pressure, are not quite accurate. These experiments were undertaken to supply information that was wanting, and to endeavour to explain the adverse symptoms recorded in the official reports of the Everest expeditions. The animals were exposed to gradual decrease of oxygen pressure such as occurs in climbing. They showed all the well-known signs of so-called acclimatisation, for example, increase of red blood cells, increased depth of breathing, etc. Some of the experiments, unlike the expeditions, did not stop at a pressure equivalent to 28,000 ft but went on to one near 30,000 ft. Some of the animals were exposed to 7-7½ per cent of an atmosphere of oxygen for eight days continuously, and recovered completely when put under normal oxygen pressure again. In spite of heroic efforts, no man has been exposed to so low a pressure for even one day, and Dr Campbell's animals hold the record for toleration of low oxygen pressure by mammals.

It is impossible to tell what is happening to the organs of man, or of animals, under such conditions without post-mortem examination. The animals exhibited loss of appetite, weakness, and air hunger such as is described in the case of the climbers in the official reports. In view of the degenerations observed in animals' tissues, it is assuming a great deal to say that the Everest climbers did not, and will not, suffer any such degeneration. In any event, no climber has lived more than a day or so above 26,000 ft, and Dr Campbell's experiments with animals indicate what is likely to happen if they do remain longer.

Mr Odell states that the animals were completely inactive and thus could not acclimatise. This is erroneous, since the most active animals showed all the signs of so-called acclimatisation, and others showed relatively as much activity as was reported by the climbers at very high altitudes. Although strenuous exercise may hasten acclimatisation, it is not essential. In the case of Norton and Somervell it was evidently considered a disadvantage. The argument cannot be used both ways. No man or other mammal has been acclimatised completely to much below ten per cent of an atmosphere of oxygen (20,000 ft), and so far as proof goes, the powers of

toleration of low oxygen are less in man than in certain other mammals, for example, in mice, rats, and rabbits.

Of course, the climbers recovered on descending the mountain, as did the animals when the oxygen was increased. It was only by examining the tissues of dead and killed animals that the damage to their organs was detected. The damage was repaired in the surviving animals when these were put under normal oxygen pressure. If any man is similar to certain of the surviving mice and rabbits, he should be able to reach the top of Everest without the use of oxygen apparatus, and recover after the descent. The results of the expeditions certainly leave the question, whether he is similar, open. It is obvious, however, that the risk is great, and the degenerations detected in the animals' tissues indicate what that risk is.

### Fertility in Hybrids between New and Old World Cottons

THE first hybrid between Asiatic and New World cottons ( $n=13 \times n=26$ ) was recorded and described by Zaitzev<sup>1, 2, 3</sup>. The parentage of this cross was *Gossypium herbaceum* (female) by *G. hirsutum* (male), and the resulting plants were, without exception, completely sterile on both female and male sides. Other workers have since confirmed Zaitzev's results. Desai<sup>4</sup> obtained a single plant of similar parentage to that described by Zaitzev. This plant was also sterile. He states that the pollen was successfully used on both parents. More recently, Vycotski<sup>5</sup> again produced hybrids between *G. herbaceum* and *G. hirsutum* which were sterile when self-pollinated and when back-crossed to the parents. Nakatomi<sup>6</sup> reported a hybrid in which the New World type ( $n=26$ ) was used as female. He found complete sterility of the hybrid, which he ascribed to irregular chromosome behaviour in meiosis.

Since 1926 several thousand crosses between Asiatic and New World cottons have been made at this Station, using various races of each both as female and male. Using Asiatics as female met with no success. Apparently sound seeds were often obtained, but these contained only minute, shrivelled embryos. Using New World as female, two hybrids were produced, and one of these, *G. barbadense*, L.  $\times$  *G. arboreum*, var. *sanguinea*, although sterile on the female side, has proved to possess some functional pollen grains, since it will cross with *G. barbadense*.

A detailed account of this interesting hybrid will be presented at a later date, and it will be sufficient to refer to a few important features.

|                 |                   |                                                                                    |
|-----------------|-------------------|------------------------------------------------------------------------------------|
| Flower Colour   | <i>sanguinea</i>  | Red, with a large and intense petal spot                                           |
|                 | <i>barbadense</i> | Yellow, with a less intense petal spot                                             |
|                 | $F_1$             | Yellow, with a red flush at the petal edges. Spot intermediate between the parents |
| Colour of Plant |                   |                                                                                    |
|                 | Body              |                                                                                    |
|                 | <i>sanguinea</i>  | Leaves red                                                                         |
|                 | <i>barbadense</i> | Leaves green                                                                       |
|                 | $F_1$             | Leaves red, but intensity reduced                                                  |

In inter-Asiatic crosses, the complex red leaf, red flower, intense petal spot is inherited as a single unit character.  $F_1$  plants exhibit reduction of anthocyanin

in the flower with certain combinations of factors, but in the *barbadense-arboreum* hybrid there is a much greater reduction of colour in the flower

In respect of other characters the  $F_1$  was intermediate, sometimes approaching one of the parents, sometimes the other

**Back-cross,  $G$  barbadense  $\times$  ( $G$  barbadense  $\times$   $G$  arboreum)**—Back-crosses were successfully made to various types of *G barbadense*. Usually only one seed per boll was obtained, and many of these either failed to germinate or gave rise to weak and abnormal seedlings which died in a few days. Ultimately eight healthy plants were raised to maturity

Of the eight plants, five showed the red-leaved character of *arboreum*, with a varying amount of red in the flower. This indicates that an Asiatic chromosome, or that part of it containing the red factor ( $R$ ), was carried by some pollen grains. A considerable weakening of the effect of the  $R$  factor was found in some of the plants. In one plant ( $F_1 \times$  barbadense, with faint petal spot) the red colour of the flower almost disappeared and the spot was considerably weakened. This suggests that the compound character, red plant body, red flower, intense petal spot, is the result of a basal gene  $R$ , for red plant body, acted upon by modifiers to produce a further development of colour in the flower

Back-crossing with a New World type results in the Asiatic modifiers being eliminated or replaced by New World factors, since if the Asiatic modifiers had been represented in *S barbadense* there would have been no reduction in flower colour or spot intensity. It is further evident that the  $R$  modifiers must be present in an almost homozygous condition throughout the Asiatic cottons, since they exhibit little or no segregation in inter-Asiatic crosses

The eight back-cross plants were again back-crossed with *G barbadense* of various types in both directions. Three plants proved to be fertile on both female and male sides, and several seedlings from the second back-cross are now being studied. The great increase in fertility of the plants in the first back-cross suggests that one or more Asiatic chromosomes may be capable of functioning in a New World plant body. If this surmise is correct, the way is opened towards the synthesis of new types of cotton combining the desirable economic characters of the New and Old World groups of cottons. The cytology of these hybrids is being investigated by Dr A Skovsted at this Station. S C HARLAND

### Spectrum of Bismuth Hydride

SOME time ago <sup>1</sup> we reported a band system  $1\Sigma^* \rightarrow 1\Sigma$  in bismuth hydride, having its origin in the vicinity of the Bi line  $\lambda 4722$ . With the aid of improved light sources, we have been able to trace this system more completely, the bands (0, 0), (0, 1), (1, 0), (1, 1), (1, 2) being analysed at high dispersion. In addition, two new band systems are now reported. In the red part of the spectrum a  $1\Sigma^* \rightarrow 1\Pi$  system appears, having a common initial state with that of the blue system. The bands here analysed are the (0, 0), (0, 1), (1, 0), (1, 2) states of vibrations

This band system is specially interesting as showing indications of a hyperfine structure due to the high nuclear spin in the bismuth atom <sup>2</sup>. Further, we observed two faint and sporadic bands at  $\lambda\lambda 4840, 5170$ ,

belonging to a new  $1\Sigma^* \rightarrow 1\Sigma$  transition, not combining with the states mentioned above. Both bands have a common initial state, very unstable as indicated by its large  $r_0$ -value and by the abrupt cut-off in the intensity of lines above  $K=5$ . Temporarily we assign this level to  $v'=0$  and the final levels to  $v''=0, 1$ . Later on we intend to make a study of the pressure effect in these bands, which bear a strong likeness to the well-known C-band in the spectrum of calcium hydride <sup>3</sup>.

Some data on the electronic states discussed above are given below

|                | $T_e$    | $\omega_e$ | $\omega_e x$ | $B_e^*$ | $-D_e \cdot 10^5$ | $a$   | $r_0 \cdot 10^8$ |
|----------------|----------|------------|--------------|---------|-------------------|-------|------------------|
| $1\Sigma$      | 0        | 1656.93    | 21.23        | 5.063   | 18.35             | 0.147 | 1.819            |
| $1\Pi$         | 4936.58  | 1693.07    | 23.87        | 5.1775  | 20.0              | 0.155 | 1.802            |
| $1\Sigma^*$    | 21278.33 | ~1678      | ~17.5        | 5.214   | 20.05             | 0.189 | 1.792            |
| $1\Sigma_p(0)$ |          | $x$        |              | 4.31    |                   |       | 1.97             |
| $1\Sigma_p(1)$ | 1313.6   | $+x$       |              | 4.20    |                   |       |                  |
| $1\Sigma_x(0)$ | 20647    | $+x$       |              | 3.88    |                   |       | 2.09             |

For the lower  $1\Sigma$  and  $1\Pi$  levels the calculated energies of dissociation, expressed in  $\text{cm}^{-1}$ , are respectively 32,500 and 30,000, and consequently they may be derived from the same state in Bi. The corresponding value for  $1\Sigma^*$  is roughly estimated to 40,000  $\text{cm}^{-1}$ . As available levels in the doublet system of Bi, fitting into these limits, we have already suggested <sup>1</sup> the  $6s^2p^3 \ ^2D_1(-47323, -43304)$  and  $6s^2p^2 \ ^7s(-26153)$  levels

On the basis of Van Vleck's theory, a study of the  $\Lambda$ -doubling in  $1\Pi$  is likely to give more detailed information regarding the electronic configuration in bismuth hydride. Our observations give

$$\Delta_{ac}(v) = 0.020K(K+1) + (T_d > T_c),$$

which does not vary to any considerable extent with  $v$

Mulliken and Christy <sup>4</sup> have recently examined a great number of  $1\Pi$ ,  $2\Sigma$ , and  $2\Pi$  states, especially those belonging to the hydrides, and stated that they stand to each other in the relation called by Van Vleck 'pure precession'. The restated relation for  $q_0$ , the coefficient of the  $\Lambda$ -doubling in  $\Pi$ , given by these authors, is

$$q_0 = \frac{2B_v^* 1(1+1)}{v(11\Sigma)} \text{ where } B_v = B_v^* - q_0$$

Assuming the precession brought about by a  $p$ -electron ( $l=1$ ) and using the values in our table above, we get

$$q_0 = 0.021,$$

in fair agreement with the observed value above

Finally, we wish to express our gratitude to the Nobel Foundation, Stockholm, for the gift of high tension transformers, which enabled us to carry through the experimental part of this work

### Nuclear Spin and Hyperfine Structure in Band Spectra

PROF E HULTHÉN <sup>1</sup> has attempted to show that the splitting of mercury hydride ( $\text{HgH}$ ) band lines into four components, as was found by me <sup>2</sup> in the (0, 0), (0, 1), (0, 2) and (0, 3) bands and by R Rydberg <sup>3</sup> in the (2, 1) and (3, 2) bands of the  $2\Pi_1 \rightarrow 2\Sigma$  electronic transition, is a normal isotope effect caused by the difference of masses between the isotopes of mercury. The failure to explain the observed line structure by the usual isotope formula he interprets

as indicating the inapplicability of this formula to a mercury hydride molecule, which forms a unique example of an unstable molecule in the  $^2\Sigma$  state Prof Hulthén further states that the isotope splittings calculated with the aid of Birge's formula (concerning the vibrational effect) show sufficient agreement with my data, and that there is no need to search for another explanation based on consideration of the magnetic and electric constitution of the nuclei

However unexpected may be the observed approximate constancy (to twenty per cent) of  $\Delta\nu$  in the wide interval of the band (0, 0) from  $\Delta\nu_{\text{rot}} = 446$  to  $\Delta\nu_{\text{rot}} = 986 \text{ cm}^{-1}$ , with regard to the prevailing influence of the rotational isotope effect in this band, nevertheless, taking in account the conformity of Prof Hulthén's calculations with my experimental data, it may be admitted that the values of splitting

FIG 1

cannot be considered as a sufficient argument in favour of my suppositions. However, it gives another argument for my assumptions not examined in my former paper,<sup>2</sup> namely, the distribution of intensity in a group of components forming a line of the band. This distribution is shown qualitatively in Fig 1 (upper diagram), where we have a curve analogous to the curves obtained with the aid of a self-recording Moll microphotometer for various lines of the mercury hydride bands. In the lower diagram is given for comparison the percentage abundance of mercury isotopes found by Aston<sup>4</sup> in his accurate measurements. The discrepancies of the two diagrams are very evident, especially if it is remembered that the strong triplet found by me was very well resolved in the region of the (0, 0) band, the resolution increasing toward the larger frequencies. It is not clear why the first component of the quadruplet appears well resolved, while with the resolving power used it ought to merge with the 199- and 200-isotopes components into a diffuse band of asymmetrical character.

The same difficulty exists concerning the results of R. Rydberg's investigations,<sup>3</sup> to which Prof Hulthén also refers. Rydberg worked with a spectrograph of a little lower resolving power than that of the Lummer-Gehrcke parallel plate used in my experiments, and has also resolved the lines of the (2, 1) and (3, 2) bands into four components, which he ascribes to the four even isotopes of mercury. On account of the relatively high percentage of the 199-isotope it appears difficult to make clear the appearance of the well-resolved 198-isotope component. It is worth noting that the amount of splitting measured by Rydberg is approximately equal to that found by me.

With regard to the above difficulties, I think that the problem can be resolved only by new investigations carried out with spectrographs of greater resolving power.

### Periodic Precipitation Structures

RECENT correspondence<sup>1</sup> has indicated that it is possible to explain the formation of periodic precipitation structures without invoking the aid of colloid-chemical principles. The amount of work which has been done on this subject is probably greater than even those who have made valuable contributions are aware. During the past ten years I have been collecting a bibliography, and I have recently had the assistance of the Science Library, South Kensington, through the kindness of Dr S. C. Bradford. My collection now contains almost five hundred references. The investigations include not only periodic structures formed by chemical double decomposition, both with and without the presence of colloids, but also those produced by salting-out, coagulation, crystallisation (from melts and from solutions), condensation, evaporation, desiccation, and sedimentation.

It may be argued that these are different phenomena, having a merely outward resemblance. Nevertheless, it is possible to explain even the most diverse types of periodic structure, assuming two conditions: (a) a critical condition for precipitation, crystallisation, or other change (supersaturation, undercooling, and a threshold concentration for coagulation are included in these conditions), (b) mobilisation of one or more of the substances (including diffusion, adsorption, capillary attraction, etc.).

It is not possible to discuss this general theory further in the space at my disposal here, but it will shortly be published in my book, "Liesegang Rings and Other Periodic Structures" (Chapman and Hall, in the press), where it is shown that in its application to the Liesegang phenomenon the theory includes those of W. Ostwald, Bradford, Dhar and Chatterji, and W. Ostwald.

ERNEST S. HEDGES

Carfax,

Urmston, Manchester

<sup>1</sup> McBain, *NATURE*, Dec 19, 1931, Friend and Vallance, *ibid.*, Feb 6, 1932.

UNLESS qualified, the views of Prof J. W. McBain,<sup>1</sup> as well as those of Drs Friend and Vallance,<sup>2</sup> are apt to convey a wrong impression. Is the colloidal state *always* not essential in periodic precipitations? Is any particular state or phase essential to these formations?

Although the electrolytic, dilution, rapid cooling, and hydroxy-organic methods make it increasingly more difficult to indicate a clear demarcation line between transient colloids and non-colloids, still a general survey of the vast number of periodic precipitations affords us cases where the colloidal state is not only absent, or not essential, but also where it is the determining factor.

The co-ordination of recent work<sup>3</sup> on periodic precipitations such as Kundt's figures and change of phase with or without chemical interaction (condensation, coagulation, salting out, evaporation, etc.) reveals the following significant facts:

1. Periodic precipitations are in general not confined to physical or chemical phenomena only, and are not restricted to any specific state or phase of matter or to any definite number of components.

2. Periodic precipitations are the material record of an undulatory movement in a mobile magma. This movement characterises generally the relationship of matter and energy, and is expressible in terms of wave mechanics.

3. As a record of change or transition, periodic precipitations are determined by the relation existing between the frequency-amplitude of undulation and

the boundaries of the system. Reducing the former, we can maintain a relationship adequate to periodic precipitation only by a corresponding reduction in the diameter of the boundary system, thus, in the case of slow movements, periodic precipitations are restricted to narrow tubes, capillaries, and ultimately large surfaces afforded by colloids.

The maxima and minima involved in this relationship find expression in practically all theories of periodic precipitation under such terms as nodes and antinodes, critical points, compression and rarefaction, under- and super-saturation, etc.

In considering the problem of periodic precipitations, we must bear in mind, however, the fact that whilst the fundamental principles of periodicity and its material records are not confined to any state or phase, the actual type and complexity of each periodic precipitation is determined by all the properties of the particular phase of matter involved in the phenomenon. This is specially the case with the colloidal state capable of functioning as either a system's boundary, medium, or component, or even all these rolled together, thus evolving the biological and mineralogical periodic structures in all their ramifications.

*J Phys Chem*, 36, 752, 1932

AFTER placing a drop of oil on a smoked glass and observing the system about an hour later, a new observation of periodic structure has been discovered.

The smoked glass under observation carried a continuous carbon film of particles about 0.2 micron in diameter, and the oil drop in slowly spreading caused the previously regular and continuous carbon film to become rearranged into alternately opaque and clear concentric rings or zones underneath the spreading drop. The effect was readily repeatable with other oil drops and smoked slides.

In every case so far observed, the central zone is a dark one, followed by a comparatively narrow, concentric, clear zone. In general, so far as trials yet go, the alternate zones are repeated several times in one experiment.

Whilst the phenomenon at once brings to mind the analogous chemical instance of periodic precipitation, it would seem to be purely physical. Oils of varying viscosity may be used, and the effect is best observed if, after carefully posing one drop of oil on the film, the glass is set down in a perfectly horizontal position. After, say, twenty-four hours, the spread oil film may be removed with carbon tetrachloride without destroying the ring structure formed in the carbon film.

Whilst, in addition to normal periodic precipitation, J W McBan<sup>1</sup> quotes work showing that periodic precipitation can occur in the absence of colloids, and E S Hedges<sup>2</sup> records the production of sodium chloride periodic structures without chemical action by salting out from solution, this is a case where periodic structures are formed in the absence of colloids, chemical action, and dissolution. Experiments and observations will be continued.

### Rate of Ionisation of the Atmosphere

THE calculation of the rate of ionisation of the atmosphere on the basis of the well-known Schweidler recombination law, by G R Wait<sup>1</sup> and J J and P J Nolan,<sup>2</sup> has shown a large variation in the rate, in the course of the day, at observing stations in Washington, D C, in the United States, and near Dublin, Ireland. It is of interest to note that the maxima of the diurnal variation curves for these stations agree closely when plotted on Greenwich Mean Time.

The Department of Terrestrial Magnetism, in connexion with its programme of study of atmospheric pollution in relation to ionisation and other atmospheric electric phenomena, has constructed, and installed on the laboratory grounds at Washington, D C, an apparatus for measuring simultaneously the small ion and large ion content from the same sample of air.

Results obtained with this apparatus permit the calculation of  $q$ , the rate of ionisation, with greater accuracy than was possible by the method employed in the previous work by Wait, in which values of nuclei content, obtained on the observatory grounds, were utilised together with values of small ion content computed from conductivity records obtained on the observatory roof. Values of  $q$  were obtained for three sets of observations in the free atmosphere on successive days in November 1931. All three days show a maximum value at approximately the same time as that previously found by Wait, as may be seen from the following table.

| Values of $q$ on 75° Mean Time |     |     |        |     |     |        |     |     |
|--------------------------------|-----|-----|--------|-----|-----|--------|-----|-----|
| Nov 23                         |     |     | Nov 24 |     |     | Nov 25 |     |     |
| hr                             | min | $q$ | hr     | min | $q$ | hr     | min | $q$ |
|                                |     |     |        |     |     | 9      | 37  | 2.0 |

|                                |     |     | 15     | 04  | 1.3 | 15     | 11  | 1.5 |
| 15                             | 28  | 1.5 | 15     | 26  | 2.5 | 15     | 34  | 1.8 |
| 15                             | 49  | 1.5 | 15     | 46  | 2.0 | 15     | 53  | 1.6 |
| 16                             | 09  | 1.6 | 16     | 07  | 3.2 | 16     | 14  | 1.5 |

The maxima in this table are about two to three times as large as the average value of  $q$ , and, furthermore, all values, including the maxima, are lower than that which is usually accepted as normal ( $q$  about 10) for most localities. Similar results were obtained by J J and P J Nolan, according to the publication already cited. It is worthy of note that, by using their modified form of the Schweidler equation on the data here discussed, the values of  $q$  are trebled and are thus brought to what appear to be more reasonable magnitudes.

Possible explanations for the variations in  $q$  have been considered. Barometric records have been examined but no correlation has been found between variations in atmospheric pressure and variations in  $q$ . Furthermore, the maximum in  $q$  is associated on only one day with a maximum in nuclei content, on the other two days it is associated with maxima in small ion content. This would indicate that the maximum in  $q$  cannot be explained by the assumption

that radioactive carriers suspended in the atmosphere become attached to nuclei and so cause increased ionisation with increase in nuclei

Finally, some consideration has been given to the possibility that the variation in  $q$  appears only because the presence and behaviour of intermediate ions have not been taken into account. Perhaps intermediate ions are present which become least numerous as the large ions become most numerous, and, further, these intermediate ions may have a much larger recombination coefficient with the small ions than have the large ions. While no data have as yet been obtained to define the part played by intermediate ions of mobility greater than 0.004 cm/sec/volt/cm, some observations have been made on intermediate ions with smaller mobilities. The results indicate that ions of this type do not vary in number in such a manner as would, if given separate consideration, produce a more constant value of  $q$  than has been shown above.

### The Highest Atomic Number

It has been suggested (I believe by Sommerfeld) that the highest possible atomic number is the constant  $hc/2\pi e^2 = 137$ . According to Eddington's theory, this number represents the number of degrees of freedom of a system of two charges. It is natural to suppose that there is a correspondence (direct or indirect) between degrees of freedom and independent wave-functions, so that the maximum number of independent wave-functions for a nucleus and satellite electron is 137. By the exclusion principle each satellite electron must be provided with an independent wave-function, so that there cannot be more than 137 of them.

In Eddington's analysis, 136 of the degrees of freedom are relativity rotations associated with the symmetrical matrix expressions  $E_a E'_b + E_b E'_a$ , where  $a$  and  $b$  have values from 1 to 16. The generalised interaction energy is  $\sum_{a=1}^{16} E_a E'_a / 137r$ , where  $r$  is the invariant proper distance of the two charges, although the portion  $\sum_{a=1}^{16} E_a E'_a / 137r$ , turns out to be of special significance in a four-dimensional space. Also, the general matrix expression associated with the interchangeability of charges is  $\sum_{a=1}^{16} E_a E'_a$ . I have found that this last expression is invariant only for 91 out of the 136 rotations, it is altered by the 45 rotations for which  $E_a, E_b$  commute and are not equal to each other or to  $E_{16} (=i)$ . Having regard to the association of wave-functions with constant energy, it is perhaps permissible to assume that wave-functions are generated only by the 91 rotations which leave the energy invariant.

If this is right, it follows that the highest possible atomic number is  $91 + 1$  instead of  $136 + 1$ , so that there can be no element beyond uranium (92).

### Possible Existence of a Neutron

In a paper to appear shortly in the *Proceedings of the Royal Society*, I have reported observations on the absorption of the radiations produced in beryllium and other light elements by bombardment with polonium  $\alpha$ -particles. The experiments indicated that the radiations emitted from beryllium, boron, and fluorine in the 'forward' direction, that is, in roughly the same directions as the  $\alpha$ -particles producing them, were less absorbable than those emitted in the backward direction. In my paper I show that this observation is very difficult to reconcile with conservation of momentum and energy if the radiations are assumed to be  $\gamma$ -radiations corresponding to the energy available.

Now that Dr Chadwick has put forward evidence for the existence of neutrons,<sup>1</sup> this difficulty appears to be solved. Thus if the radiations are assumed to consist of neutrons, it follows immediately from the conservation laws that those emitted in the forward direction must have considerably more energy (50 per cent in the case of beryllium) than those emitted in the backward direction. This suggests that the radiations from boron and fluorine, as well as that from beryllium, consist at least in part of neutrons.

### Protection of Herbarium Specimens

In making a herbarium collection of Indian types of cotton, the necessity was felt of protecting the mounted specimens from injury while handling. To meet this difficulty, the senior writer suggested using a transparent celluloid material as a covering for the specimens. 'Cellophane', 'Cellglass', 'Sidak', and other trade names are applied to such products, which are sold in sheets, and are very thin, tough, flexible, transparent, damp-proof, and inexpensive. In commerce, these materials are used for wrapping boxes of chocolates, etc.

The universal practice of mounting pressed and dried plants without protective covering has the serious disadvantage that the leaves and flowers become brittle and are liable to break off. Thus, if the specimens are constantly being examined, these losses ultimately deprive the collection of its scientific value. The celluloid tissue used, while protecting the specimens from injury and breakage, at the same time allows the observer to examine the specimens with ease, even with a lens.

The technique employed is very simple. After the specimens have been pressed and dried, they are fastened to the mounting paper with a celluloid-base cement, such as 'Durofix', an improvement which does away with the necessity of stitching or using strips of paper to keep the specimens in position. A sheet of tissue is then cut to the required size, the edges are smeared very thinly with celluloid cement, and the sheet is then laid over the specimens on the mount, to which it adheres readily.

An additional advantage is that if the celluloid tissue has been carefully applied, the risk of damage by insects is reduced.

**The Jinn in Eastern Folklore**—In the course of some notes on Arabian and Persian folklore in *Folk-Lore*, vol 41, no 4, Prof R A Nicholson points out that old Arabian pre-Islamic folklore has a character all its own, and that, notwithstanding the belief in jinn, the supernatural played a very small part in the life of the sixth-century Beduin. Belief in the jinn was made an article of faith by Mohammed, and his authority is cited for the statement that every Muslim at his birth and throughout his life is attended by a jinni or familiar spirit. Though normally invisible, they can assume any shape they please, yet so long as a spiritual being is looked upon by the human eye it cannot change its form—a belief which appears also in Irish folklore. The Muslim jinni, however, can evade the difficulty by producing a form before itself like a screen. When this is moved the eye follows it involuntarily and the jinni escapes. The jinn have much in common with our fairies. In Persia, a rite known as "The Feast for the Daughter of the Fairy King" is employed to propitiate the fairies whose wrath has been aroused, especially when this is manifested by a visitation of sickness or misfortune. Priestesses, old women acquainted with the rite, alone are allowed to perform it. A mirror, chafing dish, cup of water, some sugar-cane, collyrium, frankincense, and the egg of a black hen are carried to the top of a hill or other suitable spot which previously has been swept clean. A fire is lighted, into which seeds of rue are thrown, and incantations are chanted. At night the sick person is brought to the spot, or, if he is too ill, the objects named are carried to his bedside in a wallet. He must eat some of the sugar-cane, apply the collyrium to his eyes, and then look at his miserable face in the mirror, while he listens to the auguries which the old woman draws from the appearance of the yolk of the egg. Usually the verdict is that an entertainment must be given to the daughter of the Fairy King, so that, eating salt with the man, she may pardon his offence.

**Teleilat Ghassul**—An account of excavations carried out by Père Mallon of the Biblical Pontifical Institute, Jerusalem, in 1929-30 and 1930-31 at Teleilat Ghassul, is given by the Rev J G Duncan in *Ancient Egypt*, 1931, pt 3. The site lies about six kilometres north of the Dead Sea and about four kilometres east of Jordan, almost in the centre of the plain Arboth Moab. The number of the tells in the neighbourhood argues that the population in the copper and bronze ages was considerably more dense than it is nowadays. Of these tells, Teleilat Ghassul is one of the most ancient. The natural soil, reached at a depth of about 18 ft, is sand, an ancient sea floor. The whole ruin, including suburbs on the southern side, is 800 metres by 400 metres in extent. Four strata of occupation were found, the suburbs belonging to the latest and largest. Each city was destroyed by fire, as is demonstrated by the deposit of ashes which overlies each floor. The pottery falls into two or three classes, neolithic, and copper and bronze age, pointing to an occupation lasting from about 2500 B C to 1900-1800 B C. After the destruction of town IV by fire, the site was not re-occupied. Prof Petrie has pointed out that bronze may appear in Palestine at a date earlier than that implied by Père Mallon, which might give a date for the destruction of the town at 2100 to 2000 B C. This would strengthen Père Mallon's identification of the southern mound with Sodom. A remarkable feature of the site is the large number of inscribed stones and seals, sherds and brick which have been found. These

have not yet been deciphered, but they support the conclusion, reached on other grounds, that from the earliest to the latest settlement, notwithstanding the marks of development and transition, the same civilisation prevails. This also holds of the northern mound, which, tentatively, is identified with Gomorrah.

**Sexual Behaviour in Frogs and Toads**—In certain of the tailed amphibians it has been recognised that the chief rôle in sex recognition is played by chemical sense, but as regards the frogs, opinion has been by no means sure. Now Ch'eng-Chao Liu has made a study of the Siberian toad (*Bufo raddei*) and the pond frog (*Rana nigromaculata*), both natives of north-eastern Asia, and the result is his rejection of the chemical sense as the basis of sex recognition in these species (*Peking Nat Hist Bull*, 1931-32, vol 6, p 43). In this he confirms the observations of Noble and Farris on the American wood-frog. The author finds, regarding the frog and toad, that males appear first during the breeding season, and females ready for egg-laying are attracted by the calling croak of the males. The males appear to mate indiscriminately with whatever individual they come across, but should that happen to be a male, a new note, a croak of warning, is sounded by the lower male and this, sometimes combined with repulsive action, leads to sex recognition. When the eggs have been laid, the females escape by elongating their bodies, and thereafter they move to the land. The persistence of the male embrace is matter for wonder—on several occasions the bodies of dead males and females were offered to normal males, often the males clasped the dead bodies, and sometimes they retained their hold until the grasped bodies began to decay.

***Spirula* from the Dana Expeditions**—Prof Graham Kerr has given us a very beautiful and intensely interesting account in his "Notes upon the *Dana* Specimens of *Spirula* and upon Certain Problems of Cephalopod Morphology" (Oceanographical Reports edited by the "Dana" Committee No 8, Copenhagen). The *Dana* was fortunate in obtaining ninety-five specimens of *Spirula* in the Atlantic Ocean between 10° and 35° N lat, most of the catches being in the west Atlantic, whilst others occurred in the eastern Atlantic from the Canaries to north of the Cape Verde Islands. The live specimens have already been described by Prof Schmidt (*NATURE*, Dec 9 1922). In the orientation of the body the cephalopodium theory is definitely abandoned, and the head is regarded as anterior, the tip of the body posterior, the funnel surface ventral, and the surface opposite to the funnel dorsal. *Spirula* is in no sense a primitive form and it should be placed high up in the scale of cephalopod evolution. It is argued that the primitive cephalopod shell was spiral and not straight, and the shells of Cephalopoda—living or extinct—in which the nautiloid spiral is departed from are necessarily internal. The spherical initial chamber of *Spirula* is taken as indicating that at no stage in its life history is it external. The straightening out of the shell in its later formed portion is important as showing the beginning of progressive evolution towards a loss of the spiral, and its endogastric curve is interpreted as due to its having undergone rotation within the body. There is torsion of the posterior loop of the alimentary canal, which is believed to be a result of the rotation of the shell within the body during the phylogenetic history of *Spirula*. The radula is shown to be non-existent, the supposed radula teeth being tooth-like projections of the buccal lobes. The coelom and the male

genital organs are described in detail, the renal sacs being fused together as in other dibranchs. The whole work is full of important information and carefully thought out deductions.

**The Effects of Fixatives**—The principal conclusions of A. A. Tarkhan (*J. Roy. Mic. Soc.*, Dec 1931) on the effects of fixatives and other reagents on cell-size and tissue-bulk are as follows. Exposure of fresh organs and tissues to air produces shrinkage, hence they should be placed in the fixative as soon as excised. Formol (5-10 per cent formaldehyde) over periods of 24-48 hours does not swell tissues, but the use of formol for longer periods should be avoided on account of the toughening of the tissues and consequent difficulty in sectioning. Mercuric chloride and picric acid, in saturated aqueous solutions, are powerful shrinking agents, as is absolute alcohol. Strong solutions of chromic acid (1 per cent) and potassium bichromate (4 per cent) are similar in effect. Clearing produces slow and progressive shrinkage, and this appears to be largely independent of the fixative originally employed. Xylol and toluol shrink tissues more than benzol, and oil of cedar wood (as is generally accepted) produces the least shrinkage. Embedding in paraffin should be reduced to the shortest time consistent with penetration, for it causes progressive shrinkage which is largely in direct proportion to the temperature.

**Volume Tables for Timber of *Acacia Catechu***—The utilisation of khair (*Acacia Catechu*) trees for the production of katha (which, mixed with betel and lime, forms the *pan* so commonly chewed by Indians), in the United Provinces of India, is effected by three different agencies. The general principle consists of reducing the black heartwood of the tree to chips and then boiling the latter. The three agencies are (1) the Chais—a special class of skilled katha workers from Gond and Bahraich districts who carry out their conversion of the timber in furnaces constructed near their camps situated on streams in the forest, (2) factories—the Indian Wood Products Company, with its factory at Izatnagar, has an agreement with the Forest Department for the supply of khair from the submountain forest divisions, its conversion is closer than that of the Chais, (3) the Paharis or hill-men—their method is wasteful, as they utilise only the best parts of the heartwood, leaving the rest to rot in the forest. In vol 13, pt 9 (1929), of the *Indian Forest Records* the first volume tables were prepared for commercial timber (katha) and heartwood for khair (*Acacia Catechu*) by members of the Forest Research Institute. These tables chiefly referred to areas worked by the Chais both in the United Provinces and in Bengal. In a recent part of the *Records* (vol 15, pt 3, 1931), H. G. Champion and Ishwar Das Mahendru supplement the former work by tables for factory working. A more regular method of working, and a more detailed knowledge on the subject of the volume likely to be procurable from definite areas, became necessary when a factory depended for its continued existence upon a constant supply of raw material. In view of the considerable range in value of trees of different sizes, volume data were desirable, and the investigations comprised in these two parts of the *Records* are of very considerable practical value.

**The Izu (Japan) Earthquake of Nov 26, 1930**—Since the earthquake, a line of precise levellings has been carried round the Idu peninsula, in the northern part of the route crossing the Tanna fault. This series has lately been compared by Prof. C. Tsuboi (*Earthq. Res. Inst. Bull.*, vol 9, pp 271-290, 1931)

with that made towards the close of 1923, and the latter with a series made in 1903. It is assumed that the changes between the first and second series were due to the Kwanto earthquake of 1923, and those between the second and third to the Idu earthquake. During the latter earthquake, displacements occurred over 18.5 miles of the north-south Tanna fault. The crust on the west side of the fault, relatively to the other, was shifted about 3 ft 3 in. to the south. The vertical movement was less simple, the western block being depressed relatively at the northern end and elevated at the southern (*NATURE*, vol 128, p 551). The line of levellings across the fault shows a V-shaped depression of 7.75 in. along the fault during the Idu earthquake, but very little change during the Kwanto earthquake. Along the western side of the peninsula, Prof. Tsuboi distinguishes six land-blocks, each of which moved separately during the earthquake, but with some order in their general displacement, for the directions of their tilts, beginning with the southern block, changed in a clockwise direction. This shows that the crust as a whole was twisted like a plate, and this is also indicated by the hinge-like vertical movement along the Tanna fault.

**X-Ray Wave-Lengths**—Accurate measurements of X-ray wave-lengths are usually made with crystals or ruled gratings, and a small but important difference exists between the results. An account of an application of a third method is given by J. A. Bearden in the first January number of the *Physical Review*. He photographs the refraction spectra produced when the X-rays are dispersed by a quartz prism with an angle of 90°, obtaining remarkably precise records of the deviation, from which wave-lengths are calculated by the quantum theory of the effect. The results are almost identical with those obtained by the crystal method, but are definitely not in agreement with the ruled grating measurements. The conclusion is somewhat unexpected, as the results of different observers who have used ruled gratings appear satisfactory in most respects, and indicates a possible failure of the theory of diffraction at a ruled grating when applied to X-ray wave-lengths.

**Absorption of Hydrogen by Metals**—In various papers, recently published, Franzini has advanced the hypothesis that hydrogen which has been absorbed by metals exists therein in the dissolved and dissociated state. It seemed possible, therefore, that displacement of this hydrogen into the mass of the metal might be effected by the influence of an electric field, and such possibility has been realised in experiments made on palladium by Coehn and Specht. Further investigation of this question has now been carried out by Franzini (*Rend. Roy. Lombardy Institute*, vol 64, parts 11-15, 1931). Wires of nickel and iron, hydrogenated by being heated in an atmosphere of hydrogen, were employed, and the subsequent displacement of the hydrogen was determined by observing the variations in the electrical resistance of the metal caused thereby. With nickel, quantitative data were obtained, but with iron only qualitative evidence of the displacement of the hydrogen towards the extreme negative, when the electric field was established, was forthcoming. The increase in resistance following absorption of the hydrogen is probably due to the setting up of an e.m.f. arising by polarisation of the hydrogen protons with respect to the molecules or groups of molecules of the metal. The linking is ruptured by the electric field and the gas migrates into the metal.

**Transport Numbers**—According to the modern theory of strong electrolytes, the mobilities of the ions vary with concentration, and since this variation

is not relatively the same for all ions, but depends on the radii and valencies, the transport numbers of salts will vary with concentration. Jones and Bradshaw (*J. Amer. Chem. Soc.*, Jan.) show that a method of calculation previously applied by Jones and Dale in 1929 to barium chloride can be applied to lithium chloride, and they have determined the transport number at many different concentrations between 0.023 and 2.95 normal at 25°, finding values from 0.3272 to 0.2575 over this range. They show that the transport number  $t$  can be represented as a function of concentration  $c$  by an equation of the form  $t = [A/(1 + B\sqrt{c})] - 1$ , where  $A$  and  $B$  are constants, as was the case with barium chloride. They also recalculate the electromotive force measurements of MacInnes and Beatty with lithium chloride and show that these results can be expressed by a similar equation, the actual figures given by MacInnes and Beatty having been calculated by another, empirical, method. The activity coefficient of the ions of lithium chloride varies with the concentration according to an equation derived by Hückel. Jones and Bradshaw's paper is an important one in relation to the modern interpretation of transport numbers.

**Determination of Nitrogen in Yeast.**—It is well known to analysts that certain substances such as meat, urine, and milk, and especially those high in nitrogen, resist the oxidising action of sulphuric acid in the original Kjeldahl method for the determination of nitrogen, and that, consequently, low results are

obtained. Modifications of Kjeldahl's method have therefore been proposed, such as that of Gunning, in which the sample is digested with sulphates of potassium and copper, with or without potassium permanganate, and the Christiansen and Fulmer methods, where hydrogen peroxide is the oxidising agent. In certain cases these methods also give doubtful results, and yeast, especially if dried or pressed, is a particular offender in this respect. In connexion with his work on nitrogenous metabolism in yeast, R. S. W. Thorne (*J. Inst. Brewing*, **38**, 23; 1932) therefore found it necessary to run comparative tests by the various methods—the Dumas method, a somewhat laborious and difficult procedure, being taken as giving the true nitrogen content. The Kjeldahl-Gunning method gave the same results, though after a shorter period of digestion than Kjeldahl's original procedure, but the results showed that only 91.2-95.9 per cent of the total (Dumas) nitrogen present was determined, the actual magnitude of the error being influenced by the specific character of the yeast examined. The Christiansen and Fulmer method, however, gave 99.4-99.8 per cent of the true nitrogen, but only when the optimum quantity of hydrogen peroxide (30 c.c. of 50-volume solution for 0.5 gm. of yeast) was taken. A rather surprising feature of the work is the fact that ter Meulen's method, in which the sample is heated with a nickel catalyst in a current of hydrogen and the resulting ammonia absorbed in acid and titrated, also gave low results.

### Astronomical Topics

**Photographs Measuring the Intensity of Moonlight.**—Dr. Frederick Schembor, Vienna XI, Grillgasse 31, III/37 Austria, has sent a request that observers who possess film cameras should take pictures of the moon out of focus on the nights March 21-22 and March 22-23, that is, the nights immediately preceding and following the almost total eclipse of the moon; the eclipse occurs about 1 P.M. on March 22, and is, of course, invisible in Europe. The object is to compare the moon's illumination before and after eclipse, in order to see whether the lowering of temperature during the eclipse leaves any discernible effect some hours later. Dr. Schembor wishes a screen to be prepared with a central aperture of the same size as the object glass. The screen is to be placed close to the film, with the aperture central. The distance from lens to film is to be one-third of the focal length. Many exposures can be made on a single film, moving it sufficiently between exposures to prevent overlapping of images. Varying exposures may be given from 1/100 of a second to 1 second, but the length of each and their order must be carefully noted, also the Greenwich time (to seconds) of each exposure, with notes on the clearness of sky, the make of film and of objective, the focal length, and the distance from film to objective. The film is to be sent undeveloped to Dr. Schembor at the above address. The name, address, and longitude and latitude of the sender are also to be noted.

**Solar and Terrestrial Relationships.**—In June 1924 the International Research Council appointed a special committee to study the relation between solar and terrestrial phenomena. This committee has now published a third report of its activities, to which are attached numerous memoranda, written by members and other leading authorities, on various aspects of the subject. Several of these memoranda deal with the meaning and value of the daily character figures of various solar phenomena which have

been published during the last few years in quarterly bulletins by the International Astronomical Union. The methods employed, reasons for discrepancies between the character figures from different co-operating observatories, as well as suggestions for their improvement, are all discussed; and indications are given as to the ultimate value of results to be obtained from them. The memoranda are too many to enumerate in detail, but several that deal with changes in the ultra-violet solar radiation as related to various terrestrial phenomena (such as the amount of ozone in our atmosphere) are perhaps of special importance. The whole report affords evidence of the considerable amount of useful research accomplished by the committee since its formation, and supplies a condensed summary of the present state of knowledge in those subjects which fall within the scope of the committee.

**Mass of Neptune's Satellite.**—The recent investigation at Mount Wilson of the mass of this satellite has already been noted in this column. A paper by Prof. H. N. Russell (*Scient. Amer.*, Feb.) now gives fuller details of the research: it is illustrated by photographs of the satellites of Uranus and Neptune taken at the Yerkes Observatory. The delicacy of the research is brought home by the fact that careful allowance had to be made both for the shift in the earth's centre due to the attraction of the moon and the displacement arising from the earth's rotation. The most probable value of the mass is five times that of the moon, or  $1\frac{1}{3}$  that of Mercury (using Backlund's value for the latter, which is  $\frac{1}{3}$ th of the earth's mass) and  $\frac{1}{3}$  of that of Mars. Prof. Russell conjectures that its diameter may be 2500 miles. Unless it is larger than this, it must have a high density if the mass found is near the truth. He calls the satellite "nameless": the name *Triton*, suggested by the late Camille Flammarion, is very appropriate. It has already been accepted by many astronomers, and might well receive general recognition.

## University College, Exeter

## THE WASHINGTON SINGER LABORATORIES

THE Washington Singer laboratories at University College, Exeter, the erection of which was rendered possible by the munificence of Mr. W. Washington Singer, contain the departments of chemistry and physics, and form the first instalment of an extensive scheme of university buildings intended to be erected on the Streatham site—a magnificent setting, amid delightful surroundings, and commanding views of valley and hill unsurpassed in the country. The lay-out of the scheme is governed by the slope of the

There are three floors, the ground and first floors being devoted mainly to physics and the second to chemistry. Each floor is divided by a corridor 8 ft. wide, and in general the rooms are arranged in units, or multiples of units, in width 10 ft. between centres. On both sides of the corridors, most of the rooms are 20 ft. deep. The ferro-concrete floors have intermediate support on a double row of concrete pillars coinciding with the lines of the corridor walls, which are of brick,  $4\frac{1}{2}$  in. thick. Occupying a central position

FIG. 1.—Washington Singer Laboratories, University College, Exeter.

site, the new laboratories facing almost due south. The front elevation, overlooking the Exe valley, is severely plain and bears nothing approaching the ornate, the only feature of a decorative nature being the coats-of-arms of the counties and principal boroughs in the region which the College serves. These take the form of unobtrusive mural tablets.

There are three main entrances to the building, which is approximately 300 ft. long and 55 ft. wide. It is faced with a fine brick of inconspicuous colour, and the long span of roof carries about 100,000 Cotswold stone tiles, forming a unique feature in the south-west. Like the facing bricks with which they tone, the tiles are less conspicuous than those commonly in use, and have a much longer life. A pleasing feature of the back elevation is the Tudor windows of Portland stone, which open upon a terrace.

is a large examination hall, about 100 ft. long and 35 ft. wide. It rises to the top of the first floor and will accommodate about five hundred students.

In the provision of gas, water, and electricity in the various rooms the floor-duct system has been adopted. Horizontal ducts are also provided in the first and second floors, which not only serve the purpose of a vitiated air duct in the ventilation system, but also give means for laying rapidly any temporary cable, or piping, as required, to any room.

The supply of direct electric current to the laboratories is obtained from a 250 ampere-hours battery of 110 volts, a 150-ampere 110-volt charging generator being also available for the distribution of heavy currents. The battery is subdivided at the fifth, fifteenth, twentieth, and thirtieth cells, and is intended for the supply of small currents at reasonably constant

voltages There is a substation on the ground floor, and the Corporation of Exeter supplies 210 volts two-phase alternating current, which is distributed for light and power In addition, there is a 200 volts direct current generator and an alternator, the latter supplying alternating current of variable voltage and frequency

For the supply of compressed air and of vacuum the unit system has been preferred to that of general distribution, and any worker who requires either of them has it thus under his own control The machines in the workshop are entirely unit driven, and there is a small furnace for casting An automatic domestic telephone service is installed in a number of rooms

The ground floor contains the workshop, battery and dynamo rooms, a small magnetic laboratory, two theatres, preparation and research rooms, a spectroscopy laboratory, and cloakrooms The larger theatre, which has seating for 150 as a minimum, is fitted with electrically controlled light-tight blinds, and the smaller theatre, which adjoins it, is provided with a minimum seating for 80 The acoustic properties of both theatres have received particular consideration, and the demonstration benches are anti-vibrational, being supported on a layer of concrete, 2 ft thick, embedded in the ground and separated from the floor The fixed slate benches in the spectroscopy laboratory and in some of the research rooms are also anti-vibrational

The first floor is similar in construction and contains a large laboratory for advanced students, intermediate and advanced optics rooms, honours laboratory, private, research, glass-work, apparatus, and store rooms, together with a large laboratory for intermediate students There is also a writing-room and a library, jointly used by the students of chemistry and

physics Except in the intermediate laboratory, there are no fixed benches on the floors, those around the walls being built on brick piers which rest on the concrete floor These wall benches are of solacite—an acid- and heat-resisting material similar to slate A special feature of the physics department is the provision of numerous electrical panels in all rooms, so that each student has available, on one and the same panel, lighting, power, and direct current (variable voltage) circuits This arrangement has already proved of the greatest value and convenience

The chemistry department occupies the whole of the second floor A feature is the junior laboratory—a spacious room about 80 ft long and 35 ft wide—for intermediate and pass degree students It has places for forty-eight students There are also laboratories for physical, analytical, and organic chemistry, two lecture theatres—similar to those on the ground floor—together with preparation and store rooms In addition, there is a number of small rooms which have been especially adapted for research

Flats above the second floor are provided for the caretaker and resident engineer, while a portion of the roof is flat and available for special experiments An automatic lift completes the equipment

Owing to the national situation, no official opening has been held, but last December the Physics Department, in conjunction with representatives of the electrical industry, organised a three-days' Faraday exhibition, at which Sir William Bragg gave the inaugural lecture This exhibition, which was attended by some five thousand people, enabled the general public to inspect the laboratories, the erection of which emphasises the rapid progress and development of the College, situated as it is in a non-industrial area

### Developments of Electric Lighting

IN the February number of the *G E C Journal* there is an interesting article by H W Richardson on the progress and development made by the General Electric Company in 1931 Considerable progress has been made in perfecting striated discharge tubes for lighting In all ordinary discharge tubes containing rare gases, the glow in the main part of the tube is continuous When, however, common gases such as air or nitrogen are used, the discharge, under certain conditions, breaks up into a number of separate sections This effect is known as the striated discharge Formerly it was only possible to get this effect momentarily As a result of recent work in the G E C laboratories, this type of discharge can now be produced at will in neon, and the effects are very striking and beautiful It is still in the experimental stage

In addition, new colours in cold cathode tubes such as are used for advertising purposes have been developed Hot cathode tubes, the intensity of the light from which is much greater than that of the older cold cathode type, have not yet reached the commercial stage, but development is proceeding very satisfactorily Owing to their high efficiency as sources of coloured light, they possess special attractions for use in coloured flood-lighting and for coloured lighting generally By suitable combinations of coloured sources, light for general illumination can be produced In combination with ordinary incandescent lamps they give light almost indistinguishable from daylight The absolute efficiency of the conversion of light into power is now very high The new so-called 'ripple' effect was described in the *Journal* two years ago At the time, this effect could only be obtained in blue or green colours It has now

been possible to produce it in neon gas so as to give the well-known orange hue

The G E C laboratories have carried out a large amount of work in connexion with aviation lighting equipment A reflector type air beacon has been developed which on trial gave results closely approximating to the predetermined calculations In the new aerodrome flood-light there are nine reflectors of parabolic trough formation each equipped with 1000 watt tubular lamps With the help of a specially developed focusing device, the unit can be set up in daylight The results obtained by tests at night are very satisfactory

During the past three years commercial photometry has been passing through a transition stage All the visual methods used during the last forty or fifty years are steadily being superseded by photoelectric methods of measurement Three photoelectric photometers are at present in use at the G E C Research Laboratories which are capable of being used for several purposes They can, for example, measure the lumens on a direct reading lumen scale over a range of colour temperatures extending from 2400° K (absolute) to 2800° K approximately The lumens and colour measurements are both measured on direct reading scales, and so also are the measurement of lumens and lumens per watt These improvements save a great deal of time and greatly reduce the risk of error At the Osram lamp works a photoelectric photometer utilising a cubical photometric integrator of eight-foot side has been installed It has been designed more especially for the measurement of the very large lamps used in lighthouses, which often require 10,000 watts each

## Life and Work of William Henry Perkin

THE special honour and affection in which the late Prof W H Perkin was held by the Chemical Society is reflected in the publication of a special number of the Society's *Journal* (price 3s 6d) giving an account of the life and work of "this great master in organic chemistry". Prof Perkin, who was Longstaff medallist, first Pedler lecturer, and a past president of the Society, and had been most closely associated with the development of chemical studies and knowledge in the Universities of Manchester and Oxford, died on Sept 17, 1929.

The story of Perkin's life from the personal point of view has been written by Mr A J Greenaway, a life-long friend, and formerly editor of the Society's *Journal*, in which the results of most of his researches were published. His scientific work has been described by two of his old associates, Prof J F Thorpe, who confines himself to the Wurzburg, Munich, Edinburgh, and Manchester periods, 1880-1912, and Prof R Robinson, who discusses a selection of the subjects in the study of which Perkin was actively engaged: the constitution of berberine, brazilin and haematoxylin; harmine and harmaline, cryptopine and protopine. There is appended a bibliography of 271 papers published by Perkin and his collaborators, there are four posthumous papers on strychnine and brucine yet to be published. The book also includes three photographs of Perkin, and one of the memorial plaque presented in triplicate to the Society and the Universities of Manchester and Oxford by his colleagues and pupils.

William Henry Perkin was born on June 17, 1860, he was first sent to preparatory schools at Harrow, and later to the City of London School, chosen by his father, Sir William Perkin, founder of the coal-tar dye industry, not merely because it was his old school, but also because it was then "the only one he could find where science was taught". The science master was Henry Durham, who gave courses in chemistry, botany, and physiology alternately, and there was a practical chemistry class on Saturday afternoons, when the boys worked at the lecture table. In the garden of his father's house at Sudbury there was a hut fitted as a laboratory where the Perkin boys, W H and A G, were brought up in an atmosphere of research but without systematic instruction. In 1877, Perkin entered the Royal College of Chemistry at South Kensington and studied under Prof (later Sir Edward) Frankland and Dr W R E Hodgkinson, in 1880 he went to Wurzburg, studying chemistry under Wislicenus, physics under Kohlrausch, and mineralogy under Sandberger, and in 1882 he went to Munich to work under Baeyer. Here he established a claim to be regarded as one of the most promising of the younger chemists.

In 1887, Perkin was appointed the first professor of chemistry at the newly founded Heriot-Watt College at Edinburgh, his work on ring compounds was continued, much work on other subjects, including camphor, was undertaken, and the alkaloid investigations were commenced. The University of Manchester secured him in 1892, he then entered on what he once described as his 'golden age' of research, and his school established a world-wide reputation. Tempting offers of chairs elsewhere were refused, but in 1912, Perkin accepted the Waynflete professorship of chemistry at Oxford and a fellowship of Magdalen College. At Oxford he completely transformed the chemistry school, liberating a flood of new knowledge. Admirers of the man himself, genial and warm-hearted, and of his immense services to organic chemistry, will prize this triple tribute to his memory.

## University and Educational Intelligence

CAMBRIDGE.—Dr A G Hutchison, of Emmanuel College, has been appointed University demonstrator in mineralogy and petrology.

Dr R S Hutton, director of the British Non-Ferrous Metals Research Association, has been appointed the first Goldsmiths professor of metallurgy. Dr Hutton, who was educated at Blundell's School, Triverton, Owens College, Manchester, and the Universities of Leipzig and Paris, was lecturer in electro-metallurgy in the University of Manchester in 1900-8.

APPLICATIONS are invited by the University of Wales for five fellowships, each of the annual value of £200 and tenable for two years. The fellowships are open only to graduates of the University of Wales. Applications must reach the Registrar, University Registry, Cathays Park, Cardiff, by at latest June 1.

SCHOLARSHIPS for the encouragement of original research in sanitary science are again being offered by the Grocers Company. The value of each is £300 a year, plus an allowance for expenses in connexion with the work undertaken. Applications, upon a form supplied on request, must be received before the end of April by the Clerk to the Grocers Company, Grocers Hall, E C 2.

THE Board of Education announces that it is prepared to consider applications for full-time studentships from teachers with at least five years' teaching experience who desire financial assistance to follow courses of advanced study at universities or other institutions at home or abroad. Particulars of the awards and application forms are obtainable from the Board of Education, Whitehall, S W 1.

MEXICO'S Department of Education offers to a world, wrestling to balance its budgets, a signal example of how to achieve equal or better schooling with less outlay. In that country, it appears, rural schools are based on the idea of building up the community economically, socially, and spiritually, and there is consequently a prejudice against residential schools as alienating children from their home surroundings. However, an exception was allowed in the case of Indians afflicted with a certain disfiguring but evidently not disabling disease (*mal del pinta*), and a party of thirty-five, ranging in age from ten to eighteen years, was assembled last April on a forty-acre site at San Gabrielito and set to work to make a residential school. Arriving with nothing but a blanket each and the clothes they stood up in, they were made to construct for themselves, sleeping the while on the bare ground, with clay and timber found on the spot, a sufficient and attractive building with necessary furniture, and to make shoes, belts, hats, chairs, and other articles for sale to obtain the wherewithal to buy such clothing as they needed and could not make, and instruments for a school orchestra. Within three months, the school was in successful operation. These facts are recorded in an article contributed by Mrs Cook, chief of the special problems division of the Office of Education, Washington, to the October number of *School Life*. The same number contains a significant excerpt from an address by the Secretary of the Interior, the general drift of which is summed up in the following words: "Never was there a time when studies and experiments in the vocational training of our youth were more necessary than to-day. We must not let the fetish of cultural education interfere with an up-to-date and effective training of our children."

## Calendar of Geographical Exploration

March 14, 1864 —Lake Albert Nyanza

Sir S W Butler discovered Lake Albert Nyanza. He had set out in March 1861 upon his first tour of exploration in Central Africa "to discover the sources of the Nile, with the hope of meeting the East African expedition under captains Speke and Grant, somewhere about the Victoria Lake". He spent a year on the Sudan-Abyssinian border, and explored the Atbara and other tributaries of the Nile, proving that the Nile sediment came from Abyssinia. In 1863 he met Speke and Grant, who had discovered the sources of the Nile, but whose information suggested the possibility of the discovery of the above-mentioned lake. Though he was unable to explore its coasts fully, he examined its eastern shore and discovered the Murchison Falls.

March 15, 1846 —Huc's Travels

Évariste Régis Huc and Joseph Gabet were sent back from Lhasa by order of the Chinese Ambassador, under escort, by the rugged route to Szechwan, finally reaching Canton. Huc remained there three years and then returned to Europe. Europeans were, so far as possible, excluded from Tibet in the nineteenth century, though an English traveller, Thomas Manning, reached Lhasa in 1811–12, but left no useful records. The Abbé Huc set out for China in 1839, spent some time in the southern provinces and in Peking, and finally settled in the Valley of the Black Waters or He Shuy, just within the borders of Mongolia. There he studied the dialect and customs of the Tatars. In 1844, accompanied by J Gabet and a converted Tibetan, all three disguised as lamas, they started for Tibet from Dolon Nor. They crossed the Hwang-ho and the terrible Ordos desert, reached Kansu, recrossed the flooded Hwang-ho, and in January 1845 arrived at Tang-kuil, where they stayed eight months studying the language. A large Tibetan embassy returning from Peking allowed them to join it and they penetrated to Lhasa via the Koko Nor desert and the snow-clad mountains. They stayed in Lhasa from January to March and opened a little chapel. Huc's "*Souvenirs d'un voyage dans la Tartarie, le Thibet et la Chine*" is one of the most delightful travel books ever written.

March 17, 1796 —Japan and Sakhalin

W R Broughton, in the *Providence*, reached Nootka Sound. He had accompanied Vancouver in 1791, but had been sent back with dispatches and had obtained a commission to complete the outline of the north Pacific coast on the Asiatic side. Finding that Vancouver had returned home, Broughton returned to the Sandwich Isles, which he left in August, and sighted Japan on Sept 7. Before his return to England in 1799, Broughton surveyed the east coast of Yezo, touched at several of the Kuriles, sighted Fujiyama, examined parts of Nippon and Sakhalin, and crossed the channel which now bears his name. His voyage supplemented the work of La Pérouse, though like the latter he failed to traverse the narrowest part of the strait between Sakhalin and the main land and to reach the mouth of the Amur.

March 19, 1870 —Schweinfurth's Travels in Africa

G. Schweinfurth reached the Welle River, south of the Niam Niam country. He had started from Khartum in 1868, intending to explore the western tributaries of the Upper Nile and to record the botany of the region. He had also heard rumours of a great river that flowed to the west, south of the Niam Niam land,

which was not connected with the Nile and upon the shores of which lived a race quite distinct from the usual type of negro. When he reached the river he found that the rumours were correct. He did not realise that it was an affluent of the Ubanga, but thought that it was the upper course of the Shari, or possibly that it joined the Benue. Schweinfurth had previously explored the coasts of the Red Sea and reached Khartum through Abyssinia (1863–66). His fine descriptions of the regions through which he passed and of the people dwelling in them have become classics for the study of this part of Africa. The relation of the Welle River to the Ubanga was demonstrated in 1885 through the work of Junker and Grenfell.

## Societies and Academies

LONDON

Royal Society, March 3 —J C McLennan, A C Burton, A Pitt, and J O Wilhelm. The phenomena of superconductivity with alternating currents of high-frequency. With currents of frequency  $1.1 \times 10^7$  per second a coil of lead wire showed an abrupt loss of resistance, of relatively large amount, at a temperature that appeared to be slightly lower than the critical temperature  $7.2^\circ \text{K}$  characteristic of the transition to superconductivity, found for the same wire with direct current. With a coil of tin wire, drawn to a diameter of  $0.3 \text{ mm}$ , it was found that with direct currents the resistance of the coil began to decrease abruptly at  $3.76^\circ \text{K}$  and disappeared completely at  $3.70^\circ \text{K}$ . Experiments with the same coil with currents of frequency  $1.1 \times 10^7$  per second gave for the corresponding temperatures  $3.67^\circ \text{K}$  and  $3.61^\circ \text{K}$ . Further experiments with higher frequencies revealed depressions of the critical transition temperature increasing in amount with the frequency. Extrapolation of the transition temperature-frequency curve, which appeared to be linear for the higher frequencies, gave  $10^\circ$  per second for the frequency corresponding to  $0^\circ \text{K}$ . With tantalum wires results were obtained similar in character to those found with wires of tin and of lead. Polarisation and orientation phenomena are involved in the production of the superconducting state in metals. This electrical state appears, in part at least, to be somewhat analogous to the saturated magnetic state obtainable with ferromagnetic metals. (See also NATURE, 128, p 1004, 1931) —G I Taylor. The transport of vorticity and heat through fluids in turbulent motion. The theory that the dynamics of turbulent motion should be regarded as an effect of diffusion of vorticity rather than as a diffusion of momentum was put forward by the author in 1916, and the particular case when the whole motion is limited to two dimensions was then discussed. The analysis is now extended to three-dimensional motion, and it is shown that the 'momentum transport' theory of Reynolds and Prandtl agrees with the 'vorticity transport' theory in one case only, namely, when the turbulent motion is of a two-dimensional type, being confined to the plane perpendicular to the mean motion. When the turbulent motion as well as the mean motion is confined to two dimensions, the vorticity transport theory yields results which are quite different from those predicted by the momentum transport theory. The distribution of temperature and velocity in the wake behind a heated obstacle for the case of two-dimensional motion, when the turbulent motion is confined to the plane of the mean motion, is in accord with the vorticity transport theory —A Fage and H C H Townend. An examination of turbulent flow with an ultramicroscope

Minute particles present in tap water were intensely illuminated and viewed against a dark background. These particles were small enough to show the Brownian movement when the fluid was at rest. The illuminated particles were used to follow the motion of the fluid, and enabled the maximum values  $u_1$ ,  $v_1$ , and  $w_1$  of the three components  $u$ ,  $v$ , and  $w$  of the velocity disturbance at any point and the distribution of the mean velocity  $U$  across the pipe to be made without introducing any instruments into the fluid. At the centre of the pipe,  $u_1$ ,  $v_1$ , and  $w_1$  were approximately equal. As the wall was approached,  $v_1/U$  obtained from the velocity disturbance normal to the wall decreased to zero, whilst  $u_1/U$  and  $w_1/U$  increased. At the wall itself, whilst the flow tended to the laminar type, the motions of particles in the laminae were sinuous, even to within a distance of  $1/40,000$  in from the wall. No particle was seen to move in a rectilinear path.

Mineralogical Society, Jan 19.—L. J. Spencer. A new pallasite from Alice Springs, Central Australia. A fragment weighing 1084 grm was collected by Dr Herbert Basedow in 1924 on the north side of the MacDonnell Ranges about ten miles north of Alice Springs, and has been generously presented by him to the British Museum collection of meteorites. It is a typical pallasite, consisting of 40 per cent of olivine (with  $\text{FeO} \cdot \text{MgO} = 4 \cdot 6$ ) and 60 per cent of nickel-iron ( $\text{Fe} \cdot \text{Ni} = 12 \cdot 7$ ) with a little troilite. Small angular fragments of olivine are embedded in the kamacite, suggesting that the olivine had been broken up before the kamacite crystallised out. The granular texture of the metal also suggests that the kamacite had been broken up with the development of Neumann lines before the separation of the taenite and plessite, and that the fragments had been partly re-dissolved in the residual melt, giving the reaction-rim of taenite. The plessite eutectic separated out in the small interspaces.—Arthur Russell. An account of British mineral collectors and dealers in the seventeenth, eighteenth, and nineteenth centuries (contd). Short biographies dealing with Robert Wern Fox (1789–1877), Wilson Lowry (1762–1824), and Thomas Hogg.—M. H. Hey. Studies on the zeolites (3). Natrolite and metanatrrolite. Natrolite is shown by nine new analyses and new X-ray measurements to have a constant  $\text{Si}/\text{Al}$ -ratio and a unit-cell formula of  $\text{Na}_{16}\text{Al}_{16}\text{Si}_{24}\text{O}_{80} \cdot 16\text{H}_2\text{O}$ , in agreement with previous results.  $\text{Na}_2 \rightarrow \text{Ca}$  replacement may occur up to about 4, and  $\text{Na} \rightarrow \text{K}$  replacement up to about 2 atoms per unit-cell. Natural etch-figures in natrolite from Benallt, Carnarvonshire (a new locality for natrolite), show the symmetry to be didigonal polar ( $C_{2v}$ ). A detailed study of the optical properties of natrolite has been made. Some observations have been made on the effects of partial dehydration on the optical properties. The vapour pressure has been studied at various temperatures and degrees of dehydration, and a discontinuity in physical properties at a water content of 15 mols per unit-cell observed. Some experiments have been carried out on the base-exchange of natrolite. Optical and X-ray examinations of metanatrrolite have been made.

Royal Meteorological Society, Feb 17.—W. H. Pick. Visibility at sea. The open ocean in the eastern North Atlantic is a region of singularly good visibility, both in summer and in winter. The highest percentages of good visibilities occur with the air temperature less than the sea temperature, but the fact that high percentages of good visibilities are also obtained with air that is warmer than the sea beneath is noteworthy. With regard to wind force, the lowest percentages of good visibilities occur with

the strongest winds. The large majority of fogs occur with air temperature either greater than or equal to the sea temperature, but there is an appreciable residue that occur when the air temperature is lower than the sea temperature.—M. G. Bennett. The visual range of lights at night and its relation to the visual range of ordinary objects by day. The visual range of a point source of light is given by the formula  $(\text{Intensity} \times \text{Transmission})/(\text{Distance})^2 = \text{constant}$ . Experiments are described from which an empirical formula connecting this constant and the brightness of the background is derived.—S. E. Ashmore. The occurrence of fog with unsaturated air at Grayshott, Hants. The relation of such fogs to accompanying meteorological factors, such as wind and cloud, has been analysed. The results appear in some degree to contradict the smoke theory of unsaturated fogs.

## PARIS

Academy of Sciences, Jan 25.—Maurice Hamy. The equation obtained by equating to zero the distance of two planets which do not meet at real points.—Charles Nicolle and Charles Anderson. The sensibility of the pig to African strains of *Spirochaeta hispanicum*. The pig can contract recurrent fever from the African strains of spirochaete, but there is no appreciable symptom. No spirochaetes can be detected microscopically in the blood, but this blood is virulent to sensitive animals.—Emile Cotton. Integrals dependent on variable parameters.—C. Gutton and G. Beauvais. The high frequency discharge. Experimental study of the relation between the distance of the electrodes and the effective potential difference at which the discharge ceases.—Constant Lurquin. The generating functions of Laplace.—J. Favard. A definition of length and of area.—D. Pompeiu. Functions of two real variables.—R. Gosse. The integration of a partial differential equation.—Pasquier. The equations  $s = f(x, y, z, p, q)$  integrable by the method of Darboux.—Vladimir Bernstein. The analogy between the distribution of Julia's right lines of holomorphic functions and that of the singular points of analytical functions.—Nikola Obrechikoff. A generalisation of the Mittag-Leffler summation.—Thadée Banachiewicz. The calculation of the hypotheses in the Gauss-Encke method of the determination of orbits.—W. Swietoslawski, A. Zmaczynski, and J. Usakiewicz. The boiling point of ethyl alcohol. Three specimens of ethyl alcohol, dehydrated by different methods, gave boiling points  $78 \cdot 320^\circ$ ,  $78 \cdot 318^\circ$ , and  $78 \cdot 319^\circ \text{C}$ , as measured with an electrical resistance thermometer. This is appreciably lower than the figure given by Darbaudy and Lalande ( $78 \cdot 385^\circ$ ).—G. A. Beauvais. A point of potential stability of an isolated electrode of a triode valve.—Jean Thibaud. The production of positive ions of high velocity by multiple accelerations.—Mlle Y. Cauchois. Luminous spectra by transmission of non-canalised X-rays through a curved mica sheet.—Marcel Dufour. The astigmatism of the oblique pencil refracted by the spherical diopter.—J. P. Mathieu. The rotation of naphthylene-bisuminocamphor and the theory of Werner Kuhn. Correction to an earlier communication. There is no disagreement between the figures calculated from the author's experiments and those deduced from W. Kuhn's theory.—Roger Servant. The rotatory dispersion in the ultra-violet of the  $\alpha$ - and  $\beta$ -pinenes in solution in ethyl alcohol.—Lucien Mallet. Ionisation chambers of very small dimensions designed for the local measurement of the  $\gamma$ -radiation. The small size of the ionisation chamber described and illustrated, and its complete independence with respect to the measuring instrument, allows measurements of radiation received in a well-defined region.—A. Michel-Levy and H. Muraour. The influence of

diphenylamine, of aniline, and of certain of its derivatives on the double refraction of the nitrocelluloses—Gaston Charlot The catalytic oxidation of toluene As an indication of the course of a catalytic reaction, a gaseous mixture of air and toluene, of known composition, is passed over the catalyst at varying temperatures, and the proportions of carbon dioxide and oxygen in the issuing gases determined by the ordinary methods of gas analysis—A Perret and A M Krawczynski Some complex peroxides of hexamethylene-tetramine A description of addition products to hexamethylene-tetramine with benzoyl peroxide and with acetyl-benzoyl peroxide—Marcel Godchot and Maurice Imbert Some syntheses of glycols with ether oxide function—M Battagay and H Silbermann The anthraquinonylguanidines—A Marin and P Fallot The transgressive *Flysch* on the Riffian Palaeozoic—M Mascré and H Génot The influence of various manures on the development and alkaloid content of *Lobelia inflata*—E Lobstein and J Grumbach The study of an alkaloid extracted from the root of *Stemona tuberosa*, a Chinese-Annamese drug The name 'stemonine' is given to a new alkaloid extracted by the Stas-Otto method from this root Its composition is  $C_{22}H_{33}NO_4$ , its physical, chemical, and biological properties are described—E Roubaud The phenomena of postnymphal larval histolysis and autotrophic imaginal nutrition in *Culex pipiens*—V Pachon and R Fabre The functional rôle of the stomach gas bubble—D Auger and A Fessard The isochronisms of the action potentials of the electric nerve of the torpedo and of its effector—Maurice Fontaine The relation in marine and river fish between the proportion of inorganic phosphorus in the serum and the ossification of the skeleton—Jean Regnier and Mlle Alice Kaplan Contribution to the numerical study of microbial multiplication The influence of the number of micro-organisms planted on the velocity of their multiplication—Marcandier and Robert Pirot The presence of a virus, similar to that of exanthematic typhus, in rats from warships at Toulon—Pierre Lepine The presence in the encephalus of rats caught at Athens of a virus assuming the experimental characters of exanthematic typhus (Mexican typhus)

## LENINGRAD

Academy of Sciences—*Comptes rendus*, No 9, 1931—V Mitkevitch Practical magnetic units In addition to the 'pro-maxwell', which is a unit of magnetic flux adopted by the International Electrotechnical Commission at its meeting in Stockholm in 1930, the author proposes the following units 'pro-gilbert', for magnetomotive force, 'pro-hopkins', for magnetic resistance (the name given in honour of J Hopkinson), 'pro-gauss', for magnetic induction, and 'pro-oersted', for magnetic power—N Malkin A solution of the magnetometric problem in the case of a single surface of separation (the case of schistous deposits)—N Filipjev Lepidopterological notes (10) Specific independence of *Gracillaria betulicola* Hering The species differs in the structure of the male genitalia from *G elongella*, L—V Kistiakovsky Methods of studying the problem of corrosion of metallic parts of oil tankers Theoretical principles of the corrosion are discussed and a preliminary recommendation is made to cover the metallic parts with liquid glass, composed as follows 1 gm liquid sodium silicate, 2 gm sodium chloride, and 100 gm water—A Martynov The suborder *Permanisoptera*, nom n (Odonata), and its systematic position The name *Protanisoptera*, given by the author to the suborder including his family *Permaeschnidae*, proved to be preoccupied, and a new name is proposed instead

No 3254, Vol 129]

## Forthcoming Events

## FRIDAY, MARCH 11

ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee), at 4—Miss C H Wedgwood Stages of Economic Development in Melanesia  
ROYAL SOCIETY OF ARTS, at 4 30—Indian Meeting  
SOCIETY OF CHEMICAL INDUSTRY (Newcastle-upon-Tyne Section) (at Armstrong College, Newcastle-upon-Tyne), at 7—Annual General Meeting

## SATURDAY, MARCH 12

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Lord Rutherford of Nelson Discovery and Properties of the Electron (3)

## MONDAY, MARCH 14

BIOCHEMICAL SOCIETY (at University College), at 3—Annual General Meeting  
KING'S COLLEGE, LONDON, at 5 30—Prof Julian S Huxley Travels and Politics in Tropical East Africa (Lecture)  
INSTITUTE OF MECHANICAL ENGINEERS (Graduates' Section—London), at 6 45—Dr W H Hatfield The Strength and Behaviour of Steels at High Temperatures (Annual Lecture)  
INSTITUTE OF METALS (Scottish Local Section) (Annual General Meeting) (at 39 Elmbank Crescent, Glasgow), at 7 30—J Stirling Condenser Tubes and their Packing  
ROYAL SOCIETY OF ARTS, at 8—A E L Chorlton Oil Engine Traction (Howard Lectures) (2)

## TUESDAY, MARCH 15

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr C E Lakin The Borderlands of Medicine (Lumleian Lectures) (2)  
INSTITUTE OF INDUSTRIAL ADMINISTRATION (at Institute of Hygiene, 28 Portland Place, W 1), at 6 30—T G Rose The Management Audit (Address)  
INSTITUTE OF ELECTRICAL ENGINEERS (North Midland Centre) (at Albert Hall, Leeds), at 7 30—Prof J K Catterton-Smith Everyday Uses of Electricity (Faraday Lecture)  
INSTITUTE OF METALS (North-East Coast Local Section) (Annual General Meeting) (at Armstrong College, Newcastle-upon-Tyne), at 7 30—R D Burn Refining of Copper  
ROYAL SOCIETY OF MEDICINE (Pathology Section), at 8 30—Annual General Meeting

## WEDNESDAY, MARCH 16

SCHOOL OF ORIENTAL STUDIES, at 5 15—J H Driberg African Systems of Education (Lecture)  
SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6—Dr H A Harrison The Evaluation of Wood Pulp for Strength  
ROYAL METEOROLOGICAL SOCIETY, at 7 30—Dr B A Keen Soil Physics in Relation to Meteorology (G J Symons Memorial Lecture)  
ROYAL SOCIETY OF ARTS, at 8—Dr E F Armstrong Hydrogen and its Uses (Lecture)

## THURSDAY, MARCH 17

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr C E Lakin The Borderlands of Medicine (Lumleian Lectures) (3)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Prof J B S Haldane Heredity in Man (5)

## FRIDAY, MARCH 18

GLASGOW CHEMICAL SOCIETY (Annual General Meeting) (at Glasgow University), at 4—Prof G G Henderson Publication of Chemical Literature (Presidential Address)  
PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5—Annual General Meeting, followed by an ordinary meeting

UNIVERSITY COLLEGE, at 5 30—Prof A J Toynbee The Turks (Lecture)  
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Thomas' Café, Swansea), at 7 30—Annual Meeting  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Lord Rutherford of Nelson Recent Researches on the Gamma Rays

### SATURDAY, MARCH 19

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College for Women), at 3—F C Boon Teaching the Method of Ratio (Lecture)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Lord Rutherford of Nelson Discovery and Properties of the Electron (4)

### Congresses

MARCH 14 AND 15

GERMAN SOCIETY FOR THE INVESTIGATION OF THE CIRCULATION (at Tübingen)

Prof O Muller The Blood Pressure Disease in Swabia  
Prof von Skramlik The Blood Pressure in Animals  
Dr M Nordmann The General Pathology of the Peripheral Circulation  
Prof E Gabbe The Circulation and Utilisation of the Blood in the Periphery

MARCH 15 TO 18

INTERNATIONAL SOCIETY OF SURGERY (at Madrid)—Subjects for Discussion Non-tuberculous Pulmonary Suppuration, The Diagnosis and Treatment of Intra-spinal Tumours, The Surgery of the Oesophagus, and Recent Progress in Surgical Anaesthesia

MARCH 16 TO 18

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 10 30 A M—Reading and Discussion of Papers

## The Ready Supply of Cinchona and Quinine: an Urgent Need

UNDER the title "Ledger Bark and Red Bark", Mr J H Holland contributes, in the current number of the *Kew Bulletin of Miscellaneous Information* (No 1, 1932, pp 1-17), an important paper upon the past and present position of cinchona cultivation and quinine production. He has gathered together the salient facts relating to the availability of quinine and he presents these to us, without criticism, brought right up to date and from the varied points of view of the several parties which are most concerned.

After a short account of the introduction of cinchona from South America to India and Java—a story too well known to need repetition here—Mr Holland discusses the therapeutic value both of quinine and of the other cinchona alkaloids. Evidence is brought to show that the alkaloids other than quinine are regarded by medical experts to be, at least for some forms of malaria, quite as efficacious as quinine, which is the only cinchona alkaloid admitted to the "British Pharmacopœia". It may be pointed out that this is not just a return to the findings of the commissions in India in 1866, which recognised the value of cinchona febrifuge, but a distinct step forward. The old cinchona febrifuge was a mixture of all the alkaloids, whereas the new febrifuges, under such names as 'malarene' and 'totaquina', are the factory residues after most of the quinine has been extracted from the bark. This modern view of the value of the febrifuge is important, since, if it becomes generally accepted, it will ensure that the whole of the cinchona products can be utilised.

In the same paragraph of Mr Holland's paper, the old bogey which has so often hindered the adoption of a forward policy in the production of quinine—the synthetic substitute—is, for the present at all events, laid to rest. Beprochin and plasmoquine have now been under trial, but, although it is claimed for the latter that it effectively prevents mosquito-borne malarial infection among a group of healthy individuals who take prophylactic doses, "both are costly to produce and it does not seem at all likely that they will take the place of the natural cinchona alkaloids".

From the observations made upon the species and varieties of cinchona at present under cultivation, it is clear that *Cinchona Ledgeriana* has the highest total alkaloid content. It and its hybrids will, therefore, be the best species to plant, except in special cases where *Cinchona succirubra* or

*C. officinalis* may have to be substituted. This will apply particularly when the locality which it is desired to plant is respectively below or above the optimum elevation for *C. Ledgeriana*. In India, this is approximately from 3000 feet to 5000 feet above sea-level.

With regard to countries other than Java and India in which cinchona is now cultivated, a short explanatory note would have made the position clearer. The citation of their names without such explanation may mislead those who are not well acquainted with the circumstances, for outside Java and India, the cultivation of cinchona amounts to no more than a few acres, and sometimes only to specimen trees.

It is to be regretted also that a more complete account of the present-day production of cinchona has not been given, for this, of course, has a very important bearing upon the present situation. The plantations of Java, which yield about ninety-four per cent of the world's supply of quinine, are allotted only a few lines, and most of the information given has been taken from Sand's account in the *Malayan Journal of Agriculture* of 1922. Moreover, such facts about the present position as are recorded refer mainly to Madras, the less important area in India. The figures relating to the areas under cultivation in India and to the amount of bark produced are taken from the Government reports for the years 1928-29 and 1929-30. Unfortunately, they give no true idea of the possible or probable annual Empire yield, for this depends upon the conditions of these plantations. About this a good deal can be gathered if the reports are carefully read all through. Such information is by no means revealed by the quoted figures. Furthermore, considerable attention is paid to the 753 acres in the Anamalais, still a speculative proposition while the Government of India's undertaking at Mergui in Burma is not mentioned. The latter area is about the same size as the former, and its present state is described in reports of the Botanical Survey of India.

An important point to which Mr. Holland directs attention, however, is the fact that the cinchona industry has now little or nothing to fear from competition with the original sources of bark in South America.

The main purpose of the paper is to produce evidence of the need for the expansion of cinchona cultivation, to indicate the regions in which it might successfully be grown, to point to the most profitable species to cultivate, and thus to stimulate action by the grower, the manufacturer, and the

user, which will result in an adequate supply of quinine at a price that will permit of its universal use by the malaria-stricken millions of the world. Having made these points, Mr. Holland leaves us to draw our own conclusions.

We have already published in *NATURE* (vol. 124, p. 881, 1929) an article upon the importance of this subject from the Empire point of view. As was pointed out there, the British Empire includes a large proportion of the malarial tracts of the world, and the late Sir Andrew Balfour estimated that the direct annual loss to the Empire by sickness and death due to malaria is between fifty-two and sixty-two million pounds sterling. The international aspect of malaria is shown by the fact that the League of Nations has set up an organisation for antimalarial work. There should be no need to lay further stress upon the necessity of increasing the production of cinchona and quinine. A perusal of the recent reports of the departments of the Governments of India, Bengal, and Madras, the only producers of quinine within the Empire, will show the present condition of our industry. The older plantation enclosures in Madras and Bengal, which extend to a good many square miles, have been entirely planted, so far as the land within them is suitable for cinchona. Fresh soil is no longer available, some years ago it became entirely exhausted. Unless an area be fallowed for a long period in forest, it will not produce a second satisfactory crop of cinchona. The present harvests are largely from the bark of dead and dying trees. Successful cultivation in the Anamalais is as yet by no means assured, and the Mergui area cannot be regarded as at all approaching a first-class area.

There has been no systematic working scheme, staffs are denuded, and research has been almost neglected. Our supplies will shortly decrease for lack of a forward policy under a single central control. Yet it has been estimated that, if India were to supply even her own needs, she would have to increase her output by eighteen times. What of the rest of the Empire? With the passage of time, land suitable for cinchona (and it has to be very carefully selected) has become more and more scarce.

Surely the time has come when steps should be taken to stimulate action. There is here a case which seems to call for active encouragement and aid in organisation, possibly by a small Commission set up by the Government at home which would survey the possibilities of producing cinchona, not only in India, but also in other parts of the British Empire.

### The Politics of Science

*What are We to do with our Lives?* By H. G. Wells  
Pp vi+148 (London William Heinemann,  
Ltd, 1932) 3s 6d net

THERE is nowadays scarcely an issue of *NATURE* which does not call upon scientific men to unite for ends beyond the specialised discussion of their own work. That the appeal does not entirely fail of response is shown by the slowly growing professional and social organisation of the scientific world and by the formation of propagandist societies which seek to impress upon the general public the importance of science in industry and government.

All this activity indicates a growing conviction among scientific men that science has something to contribute to the modern world beyond her technical applications—that its spirit and method carry with them implications of a rule of life, for human society as well as for the individual, and of a vision for the lack of which the people perish.

The practical working out of this increasing desire for a political movement based on science has proved, however, unexpectedly difficult. Scientific men are inevitably busy and preoccupied, and by the standard of their needs they are poor. Their calling has in the past made for a high degree of individualism; they have been able to combine for discussion and publication but for very little else. Moreover, the tradition of the pioneers who worked for knowledge and disdained its material prizes has prevented the development of the powerful 'trade union' types of organisation which have elsewhere provided the economic foundations of policy. A far more serious obstacle has been that the world of science has never made up its mind what it wants from politics. It has never got within sight of a political programme of its own, and it appears to accept conventional party divisions as real and important just when the general deliquescence of politics has revealed them as the superficial things they are.

The book at present under review, though addressed to intelligent people in general and not specifically to scientific workers, is an attempt to impose the implications of science on the social and political world of to-day. Its distinguished author, himself a scientific man turned publicist, is perhaps more fitted than any other living writer to point the moral of our present discontents and to formulate political intentions for the world of science.

This book is really a highly concentrated essence,

distilled from the author's sociological writings of the last twenty years. It looks back to the Samurai—the voluntary aristocracy of "A Modern Utopia"—and to the imagined State in "Men like Gods"—"whose education was its government." It considers and rejects the experimental anthropomorphism of "God the Invisible King", and it carries on the scepticism about democratic institutions which has marked Mr Wells's writings ever since "The New Machiavelli." It contains no new fundamental ideas, but it is mature and articulated beyond any other sociological book its author has produced, and it makes, very explicitly and with complete seriousness, a most daring proposal.

When, towards the close of the War, Mr Wells sat down to consider what mankind must do to prevent the recurrence of that colossal tragedy, he discovered that, despite a respectable array of 'qualifications', he was very much at sea about a number of things which a properly educated citizen of the world ought to know. Fortunate in the possession of leisure and opportunity, he set to work, with the help of a number of distinguished specialists, to complete his education, and the result was three very important books the writing of which has left its mark on that at present under review. "The Outline of History" sought to tell the story of mankind from the primeval lair to the Peace of Versailles. "The Science of Life" recounts what is known of biology, especially in relation to human affairs, and "The Work, Wealth, and Happiness of Mankind" deals with the ways in which humanity earns its living at the present day. These three works form together a first draft of the necessary humanistic education of the future, and in the writing of them the author's distinctive political ideas have gained clarity and precision.

The present work, which replaces an earlier sketch called "The Open Conspiracy", contains the general conclusions of this mind-clearing process. It is a plan of world reconstruction made necessary by science and conceived in the scientific spirit. It does not claim to start a new movement. It is presented as a statement of a general tendency which its author perceives in the minds of intelligent contemporaries.

Mr Wells maintains that the changes in the scale of effective human association which have been brought about by scientific discovery necessitate certain wide innovations in social structure and policy if mankind is to survive, let alone to profit fully by the possibilities which modern knowledge holds out. The realisation of these innovations, he asserts, is likely to become an

increasing preoccupation of intelligent people the world over, and in the service of these developing ideas we may hope to find expression and significance for our individual lives

To this convergence of the creative intelligence of our race upon the political problems which science has set us to solve Mr Wells gives the name of 'The Open Conspiracy', *conspiracy* because it is conceived as a revolutionary movement paying no superstitious respect to established constitutional usages, and *open* because its principal method is the frank discussion and publicly announced intention which have long been the practice of the scientific world. His proposal is that constructively-minded people should deliberately and progressively possess themselves of the nerve-centres of the world in order to establish a responsible world directorate in control of human affairs

The first necessity for the Open Conspiracy arises from the technical evolution of modern warfare. What in pre-scientific ages was a relatively harmless bickering of governments has now become a danger which threatens the very life of civilised mankind, and the sixty or seventy sovereign States, with their arms and flags and their propaganda of separatist loyalties, have proved themselves an impossible method of government in a world which every day becomes more complete in its interdependence. The Open Conspirator, therefore, will work for the ending of war in the only way whereby war can be made finally impossible: by the ending of national governments the peculiar sovereignty of which consists in their right of ultimate resort of arms

It is not only war, however, which science has rendered inadmissible in the modern world. The industrial and financial anarchy which condemns that world to penury in the presence of plenty must also give place to comprehensive and responsible direction. Our major economic concerns, such as credit, fuel, power, transport, and food, can no longer be left to chaotic competitive production on an alleged basis of profit-seeking. They must become the objects of organised production for use.

This, however, does not mean that these matters must be subject to popularly elected committees or councils or parliaments at the mercy of an ill-informed and only intermittently attentive electorate. Mr Wells maintains that real control should be in the hands of those who are sufficiently interested to exercise it seriously and competently. This control should be rendered responsible, not through elections made ridiculous by the arts of the politician, but through public criticism such as

at present prevails in the scientific world. This rather startling proposal, which breaks sharply both with political and with industrial practice in Britain, merits a much more careful examination than is possible here. It recalls certain features of the social organisation of the Soviet Union and the Italian Corporative State—neither of which can be dismissed as a mere tyranny—and is curiously paralleled by a suggestion put forward some years ago over the signature of Mr Lloyd George, that industrial concerns should be made responsible simply by the statutory publication of very full information about their activities.

In the third place, the Open Conspirator must take account of population in a way which no previous statesmanship has dared to do. He must take steps to prevent any such uncontrolled increase in numbers as would cash in mere low-grade proliferation the material abundance which science offers to mankind. It is suggested that universal knowledge of contraceptive methods, combined with quite minor changes in our social and economic arrangements, would relieve us of the present fear of over-population even in India and the East, and would also rob the practice of birth control of its dysgenic effects.

The Open Conspirator thus comes into necessary conflict with various religious and obscurantist bodies which at present seek to restrict the use of these important inventions in human biology. This, because of the value he attaches to free, abundant, and competent discussion and to the fullest diffusion of authenticated knowledge, he will in no wise regret. He will welcome also every opportunity to foster sound non-tendencious education. He will make no truce with those who seek to use the common schools to inculcate nationalism or obstructive theological dogmas, or who set up barriers against the dissemination of modern knowledge. He will work for an education which will liberate minds instead of repressing them, and will answer the natural curiosities of questing youth by telling, as completely as contemporary knowledge makes possible, the place and task of the new generation in the world-wide drama of mankind.

There is nothing essentially new about all this. The dream of a world ordered and peaceful, of mankind deliberately grasping its opportunities and rising to the measure of its great occasions, has gleamed ever and again in literature and statecraft since the Hebrew prophet spoke of nations which "should learn war no more." What is new is the sense of urgency, of an imminent choice

between world order and a disastrous retrogression from all the fine possibilities of the present day, and the conviction that a growing minority of intelligent people must add to their personal concerns an overriding solicitude about the unification of the world, must work for it and shape their careers towards it, and find in the promise of it their justification and significance L A F

### A New History of the Middle Ages

*The Middle Ages, 300-1500* By Prof James Westfall Thompson Vol 1 Pp xxx+618 Vol 2 Pp vii + 619-1069 + xlv 42s net Abridged edition Pp xii + 466 21s net (London Kegan Paul and Co, Ltd, 1931)

WE owe to an American professor what is probably the best extant account of the Middle Ages as a whole, in English and in moderate compass. Prof Westfall Thompson was a pupil of Luchaire in Paris, and no doubt it is partly due to this fact that he maintains throughout the European aspect of the medieval period, which is so essential and at the same time so rare in popular general books written on it in English. One gains quite a new and a truer point of view about almost every part of the subject—feudalism, the rise of the towns, the Hundred Years' War, Flanders and the woollen trade—if one looks at it from the centre and not from the circumference. At the same time, it must not be thought for a moment that the author is anti-English. On the contrary, he is specially strong on the part played by English—and Irish—missionaries in spreading education and civilising the West. Where one feels a lack—and it is the same in Mr H G Wells's "Outline"—is on the side of the superior English political development. It is well to know that in the earliest stage all the rising European monarchies had their 'curia regis' and the germs of a national assembly. But it is important also to realise how it came about that in England the nobles identified themselves with the national cause, whereas abroad it was left for the monarch to speak for the State. No doubt Prof Thompson is well aware of this, and he probably omits it because it is so well known to English readers. But, all the same, it is a serious lacuna.

For the rest, one has little but praise to express. The author's learning is most extensive, and he refers in full bibliographies at the end of each chapter also to the most accessible modern books. He was a considerable contributor to the "Cambridge Medieval History", and has had the great

good sense to wait until that monumental collective work was completed before offering a general conspectus from one pen and one co-ordinating mind. The difference in the effect on the reader is most marked. One only refers to the great compilations, to which we are now accustomed, in order to look up some particular point or see what one man thinks about one problem. But when a reader has once started this book, though it is well packed with facts, he is drawn on, the author is so full of his subject and so keen on its interest and importance that he holds attention from beginning to end.

Where the author fixes the beginning and where the end, are also interesting points. He begins with a sketch of the Roman Empire at the time when it was being permeated by Christianity, and his last sentence is one from Erasmus on the eve of the Reformation. "'In this part of the world,' wrote Erasmus in 1517, 'I am afraid a great revolution is impending.' He was right." From which it appears that to Prof Westfall Thompson the medieval Church is the central thread of medieval history, and he also is right.

The book should, however, commend itself specially to readers of NATURE by the due space and appreciation assigned to the intellectual development, both in physical science itself and in general philosophy. The author analyses these carefully, and by frequent quotations from George Sarton shows that he is in touch with the chief repository of such learning, certainly in the United States, if not in the whole world. He discards the contemptuous view of the scientific attainments of the Middle Ages at their best, and is at pains to show that, though the masses everywhere were subject to the wildest superstitions, individual great minds were grappling with the deepest questions and in many cases anticipated, not indeed particular physical discoveries, but profound general ideas of later date.

In this matter, the contrast which is drawn between the contributions of Germany and Italy towards the end of the period is instructive and interesting. The author holds that it is to the reflective German minds of the last centuries of the Middle Ages that one must look for the origin of the development of pure scientific thought. In Germany and not in Italy one finds the unbroken line of great scientific thinkers, from Albertus Magnus—a German count—onwards to Copernicus, a Germanised Pole. In the last part of the fifteenth century the University of Cracow was ahead of Prague or Heidelberg, and as Poland was always

in close touch with Italy, largely through the University of Padua, it was German science, via Polish scholars, that at last awakened the spirit of scientific research in Renaissance Italy in the sixteenth century. Thus Galileo comes out at the end of one apostolic succession to become the first of another, and we may realise the inter-connectedness of us all.

The rôle of Italy in art was otherwise determined and more universally operative. It still contained, after all the ravages of the barbarian wars, by far the largest collection of ancient works of art in the West, and, being in touch both with Germany through the imperial connexion and with the East through Venice and the Crusades, it served as a radiating centre for all the art-forms of the later Middle Ages. The book has a few typical illustrations of comparative churches of Romanesque and Gothic style, and an abundance of good clear maps in colour, printed in Germany.

We have picked out for notice a few of the features specially congenial to readers of *NATURE*, but it should be understood that the author himself seems to be as many-sided as history. He is particularly enlightening on the battles of the Hundred Years' War and is an expert on armour, and his account of Joan of Arc strikes us as the justest and the most poignant rendering of that immortal and yet almost unbearable story perhaps possible in half a dozen pages.

There is issued at the same time an adequate and very competently abridged edition in one volume for college use. This retains all the main features of the larger work, including its excellent maps, it is only shortened by leaving out a number of personal details and certain political and military events.

F. S. MARVIN

### Science as one of the Humanities

*The History of Science and the New Humanism*. By George Sarton. Pp 178 (New York: Henry Holt and Co., 1931). 2 dollars.

IN his recent book on "Clothes", Mr. Eric Gill says that "in our hearts we know science for what it is—the greatest frivolity of history." If it was not that science enables a lot of people to get rich it would now be what it was before—the amusing hobby of charming old fools. While this statement is no doubt intended to be deliberately provocative, it unfortunately represents—if only in caricature—the opinion of many otherwise cultured men and women, who have somewhat surprisingly failed to realise that science is as essential

ally concerned with the philosophic values and the 'eternal ideas' as any other department of human intellectual activity. As followers of science, we know that the reproach is entirely unjustifiable, but to refute it is by no means easy. The difficulty lies mainly in the fact that, while the material results of science are immediately obvious, the philosophic framework of science, its methods, its aims, and the rigorous discipline of the laboratory, are scarcely to be comprehended, or even imagined, except by those who have had some considerable personal experience of scientific work. It is, however, clearly of the first importance that, in a world for which science has opened strange new vistas, and upon which she has conferred the power of limitless exploitation of natural resources, misconceptions of the ultimate character of science and misapplications of scientific knowledge should be removed as completely as possible.

This is one of the problems that Dr. Sarton discusses in his latest book, which, though slight in bulk, is a very valuable contribution to educational thought. He regards the difference of outlook between men of letters, historians, philosophers, the "so-called humanists", on one side, and men of science on the other, as "the most ominous conflict of our time." No simple solution appears possible, but much might be done by a wider teaching of the history of science, since this affords a means of conveying to humanity the real significance of science and its cultural value, which far transcends all its applications. Dr. Sarton rightly emphasises the fact that "there are no natural sciences as opposed to humanities, every branch of science or learning is just as natural or as humane as you make it. Show the deep human interest of science and the study of it becomes the best vehicle of humanism one could devise." If, as many will agree with Dr. Sarton in believing, such a desirable result may be largely achieved by a more general inclusion of the history of science in educational schemes, it would be folly to neglect a tool that lies so ready to our hands. Much has indeed already been done, but more remains to be accomplished.

Dr. Sarton is, however, too wise to believe that misvaluation of science is confined to the humanists, or that the faults are all on one side. Though, as he rather bitterly remarks, "science teachers are not expected to impart any education, but simply to teach their own technicalities", he is by no means sure that the science teachers themselves are not partly to blame for the invidious distinction between 'scientific' and 'cultural' courses. The man of science is too often aloof, assertive, self-

righteous, and incapable of appreciating branches of study outside his own, in short, he suffers from many of the very defects he rebukes in others. The remedy that Dr Sarton would apply is again the study of history—not necessarily the history of science alone, though a modicum of the latter is essential. He would like to see a solid literary and artistic basis and an insistence on the historical point of view in all scientific education, while the more literary-minded students would receive frequent explanations of scientific methods by men familiar with the history of science.

The main theme of the book is, indeed, a plea for a true cultural synthesis as the best help for the present and the most hopeful prospect for the future. The unity of mankind, as it emerges from a study of the development of civilisation in all its aspects, is the lesson the teacher should strive to impart, and though there must be specialists, there should be no specialist unaware of the unity of knowledge and unappreciative of the work of others.

Dr Sarton is concerned with more than generalities and vague indications of the path to be followed. He supports his thesis with detailed suggestions for educational schemes, and since these are both practicable and most carefully thought out, they demand the serious consideration of everyone who has the intellectual welfare of the race at heart. To humanise knowledge and to integrate it must be the earnest desire of every reflective man, and Dr Sarton has shown us how that desire might be accomplished.

E J HOLMYARD

### Short Reviews

*Catalogue of Latin and Vernacular Alchemical Manuscripts in Great Britain and Ireland dating from before the XVI Century* By Dorothea Waley Singer, assisted by Annie Anderson and by Robina Addis. Vol. 3. Pp. iii+757-1179. (Brussels: Union Académique Internationale, 1931.) 15 Belgas.

THE third volume of Mrs Singer's monumental catalogue of alchemical manuscripts in the British Isles mainly consists of indexes, with corrections and addenda to earlier descriptions. The indexes comprise a list of first lines of every tract described in the catalogue—a feature of the greatest use to students in every country, a list of every person, whether author, scribe, or owner, mentioned in them, and a list of the manuscripts classified under the libraries where they are to be seen, and containing much incidental information concerning them. In brief, nothing has been neglected which could make the work more valuable to those likely to use it, and Mrs Singer is to be congratulated heartily on so complete a piece of work.

No 3255, Vol. 129]

Two sections are prefixed to the book, the first dealing with a curious work known as *Kyrannides*, just over the border-line between alchemy and magic, the second dealing with legal documents on its history. Of these, one is specially interesting as bearing on a legend preserved by Camden in his "Remaines concerning Britaine", where he says of the first gold noble, coined by Edward III. of pure gold in 1343 or soon after, "which our Alchemists do affirm (as an unwritten verity) was made by projection or multiplication Alchimicale of Raymond Lully in the Tower of London." In 1350, four prisoners were brought into the King's Bench from the Tower. One of them, who had been in prison for seven and a half years, had received 500 écus of gold and twenty pounds of silver from the Treasury to make gold by alchemy. There can be no doubt that this was the foundation of the Lully legend.

Another interesting entry is that of a very strong Royal Commission in 1457 to examine and report on the merits of alchemy and the elixir. Its report has never been found, but it is not impossible that it still lies somewhere in the Record Office. As gold-making was illegal, and continued to be so until 1689, a number of licences to practise the art were granted. The number of manuscripts in fifteenth century English testifies to a wide interest in the subject. It is a curious chapter in the history of science.

R. S.

*The Physiology of Beauty* By Arthur Sewell. Pp. xiv+194. (London: Kegan Paul and Co., Ltd., 1931.) 8s 6d net.

THE modern mechanist—the 'publicist', to adopt the term used by Prof. Hogben, who contributes an introduction to this book—has never claimed that all the activities of living matter are to-day capable of being 'explained' on physico-chemical lines, or even that they ever will be. But he does hold it to be possible, and even likely, that the behaviour of living organisms will one day be describable in the same terms, by means of the same symbols, and in the light of the same laws as are available to describe the phenomena of the inorganic world.

The possibility of applying to æsthetic responses any methods of analysis comparable with those used in pure science has in general been ridiculed by the anti-mechanists.

To the best of our knowledge, Mr Sewell is the first to attempt, in anything like a systematic manner, to apply to these responses the ideas of behaviourist philosophy and the concept of the conditioned reflex. He has done so with courage, humour, knowledge, and, so far as the complexity of his subject permitted, remarkable lucidity. Perhaps a disproportionate section of his book is devoted to discussing the "physiology of truth" and the "physiology of good", at the expense of the actual subject promised by his title. This is analysed in Part IV, but with such tantalising brevity that another book in which ethics and epistemology have a relatively much smaller share is much to be hoped for, so that he may further

develop the idea of "biological utility" in æsthetic responses and his purely extrospective technique.

Those who are emotionally anti-mechanist, who have been conditioned against even sympathy with the publicist attitude, will do well to ignore this book. It is difficult to see how they will be able to reply to much of it. But those who realise that their enjoyment of poetry, painting, music, and the other arts will in no wise be impaired by correct analysis of that enjoyment, and who prefer an objective to an introspective analysis, should welcome the publication of Mr Sewell's book.

A. L. B.

*The House of Industry a New Estate of the Realm*

By S. G. Hobson. Pp. xxviii + 113. (London: P. S. King and Son, Ltd., 1931.) 1s.

SUPERFICIALLY "The House of Industry" is but another name for the House of Lords, become the chief cornerstone in the logical evolution of the ever-increasing tendency of the House of Commons to turn its economic problems over to independent 'commissions' for solution. Actually it is a British version of the Soviet Central Committee.

In his effort to make the suggestion palatable to a people to whom property rights are regarded as sacred, Mr Hobson has left several unbridged gaps between the idea and its practical application. The House of Industry is a new name for a metamorphosed House of Lords, but the House of Industry is to be partly selected and partly elected "by groups differently graded in the industrial hierarchy". How are the groups to be graded? Who is to grade them? How will the selection and election be carried out? He does not say, nor how he will ensure the selection and election of men competent to handle economic problems. As to how the peers and people are to be convinced that the elected-selected House of Industry is in apostolic succession to the hereditary House of Lords, he is also vague.

However, concede the House of Industry established: it must be stable, with no interest beyond the needs of industry (including the worker). A selected body might be so—the judiciary is beyond reproach—but can the elected portion ever be free from the influence of its electors? And if so, why elect?

To ensure efficiency, the House of Industry is to be free of the technicalities intended to safeguard democracy, but it is to be subject to the veto of the Commons, which will remain subject to those technicalities.

The idea is interesting. It is ably advocated. But is it sound? One is not yet convinced.

*Grundprobleme der Geologie eine Einführung in geologisches Denken*. Von Prof. Siegfried von Bubnoff. Pp. viii + 237. (Berlin: Gebrüder Borntraeger, 1931.) 11.60 gold marks.

THE flood of German geological literature that began after the War continues to rise so rapidly that many worthy contributions must perforce be given scant attention by geologists to whose special interests they do not immediately refer. It is

therefore important to insist upon the outstanding virtues of this short but brilliant book by Prof. von Bubnoff. As a philosophical treatment of the methods and fundamental problems of geology it is unsurpassed, and it is not too much to say that no geologist, be he practitioner, teacher, or advanced student, could fail to profit from a careful reading of this stimulating, clearly expressed, and fair-minded survey of his subject.

Prof. Bubnoff's style is lucid and his vocabulary can be quickly mastered; his German presents no terrors and need not deter even those who usually struggle along with difficulty. The book will richly repay a sustained effort to master its contents. The first part deals with the epistemological basis of geology, the second with the interpretation of the rocky pages of the earth's long history, the third with the measurement of geological time, the fourth with the tectonic conceptions embodied in such terms as shields, stable shelves and mobile shelves, and geosynclines, and the fifth with the structure of the earth and its crustal movements. The present state of our knowledge of sedimentation, igneous activity, metamorphism, mountain-building, isostasy, and continental drift is expressed with admirable detachment from particular doctrines. Modern theories are ably discussed and critically analysed with equal emphasis on their successes and failures. There is a tendency to favour internal mobility as the cause of crustal movements on the lines suggested by Ampferer and Schwinner on the Continent and by Bull and Holmes in Great Britain, but with a cool recognition that the problems involved are still far from being satisfactorily solved.

The book is of quite unique value. Nothing like it in scope and temper has hitherto appeared, and an English translation would undoubtedly be very widely welcomed.

*The Genesis of Cancer*. By W. Sampson Handley. (The Anglo-French Library of Medical and Biological Science.) Pp. xix + 258 + 88 plates. (London: Kegan Paul and Co., Ltd., 1931.) 21s. net.

MR. SAMPSON HANDLEY draws his data from the experiences of a curious and progressive practical surgeon, and is concerned to define the anatomical conditions which underlie the beginnings of cancers. He finds that the feature which is common to all precancerous states is an inflammation of the smaller and mostly terminal lymphatics, leading to lymph stasis, and he upholds his thesis by the detailed histology of a considerable variety of lesions—warts and adenomata, lupus and its malignant development, chronic mastitis, skin irritation in general, especially dermatoses from tar and oil, X-rays, and radium.

The changes in the connective tissue which Mr. Handley describes are, of course, well known. He differs from most other observers in judging that they precede rather than follow cancer, and adduces much striking evidence in favour of his contention. Why exactly chronic lymph stasis should lead to cancer, he does not explain. At the moment, it is scarcely reasonable to expect him to do so.

## The Expanding Universe\*

By SIR ARTHUR EDDINGTON, F R S

IN recent years the line-of-sight velocities of about ninety of the spiral nebulae have been measured. The distances of some of the nearest of them have been determined by a fairly trustworthy method, and for others rude estimates depending on statistical methods are available. When we survey these data, a remarkable state of affairs is revealed. The spiral nebulae are almost unanimously running away from us, moreover, the greater the distance the greater the speed of recession. The law of increase is found to be fairly regular, the speed being simply proportional to the distance. The progression has been traced up to a distance of more than 100 million light-years, where the recession is 20,000 km per sec—about the speed of an  $\alpha$ -particle.

At first sight this looks as though the spiral nebulae had a rather pointed aversion to our society, but a little consideration will show that the phenomenon is merely a uniform dilation of the system and is not specially directed at us. If this room were suddenly to expand to twice its present size, the seats separating in proportion, you would notice that everyone in the room had moved away from *you*. Your neighbour who was 3 feet away has become 6 feet away, the man over yonder who was 20 feet away is now 40 feet away. Each has moved proportionately to his distance from you, which is precisely what the spiral nebulae are observed to be doing. The motion is not directed from any one centre, but is a general expansion, such that each individual observes every other individual to be receding.

In 1917, before any hint of this phenomenon had been obtained from observation, Prof. W de Sitter was on the look out for something of the kind. He found that, on one of two alternative hypotheses arising out of Einstein's relativity theory, the light of very remote objects should be displaced to the red as though they were moving away from us, and he suggested the observed motions of the spiral nebulae (by far the most remote objects known) as a discriminating test. At that time, only three radial velocities had been published, and they rather lamely supported his hypothesis by a majority of 2 to 1. The majority has now become about 85 to 5, and the five exceptions are nebulae close to us which in any case should have had only small receding velocities. De Sitter's theory has been developed and modified by Friedman and Lemaître, the modern view of it is as follows.

Einstein's law of gravitation contains a term called the 'cosmical term' which is extremely small in ordinary applications to the solar system, etc., and is generally neglected. The term, however, actually represents a repulsive force directly proportional to the distance, so that however small it may be in ordinary applications, if we go

to distances sufficiently great it must ultimately become important. It is this cosmical repulsion which is, we believe, the cause of the expansion of the great system of the nebulae. The repulsion may be to some extent counterbalanced by the ordinary gravitational attraction of the nebulae on one another. This countervailing attraction will become weaker as the expansion increases and the nebulae become farther apart. It seems likely that the universe started with a balance between gravitational attraction and cosmical repulsion, this equilibrium state is called an 'Einstein universe'. But it can be shown that the Einstein universe is unstable, and the slightest disturbance will cause either the repulsion or the gravitation to gain the upper hand, so as to topple the system into a state of continually increasing expansion or continually increasing contraction. Apparently, expansion won the initial struggle, and as the nebulae spread apart, the opposition of gravitation became less and less, until now it is comparatively insignificant.

We see, then, that according to observation the system of the spiral nebulae is expanding, and that relativity theory had foreseen just such an expansion (except that as an alternative it would have been content with an equally regular contraction). What better agreement could we desire? Nevertheless, there were some misgivings which I would not by any means condemn as unreasonable. It is true that theory predicted an effect of the kind observed, but it did not say how rapid the expansion would be. It expressed it in terms of an unknown 'cosmical constant'  $\lambda$ , leaving  $\lambda$  to be determined by observation. Now the rate of expansion indicated by observation comes to us as a great shock. The universe is expanding so as to double its dimensions every 1300 million years, that is no more than the period of geological time. Astronomers, who had been picturing a slow evolution of the stars extending over billions of years, would scarcely believe our staid old universe capable of such a hustle. In fact, it means a cut of something like ninety-nine per cent in our time-scale, which even in these days of economy cuts is not to be accepted lightly by the department concerned. For this reason many have thought that the receding motions of the spiral nebulae cannot be accepted as genuine, and that the whole phenomenon must be explained away as a misinterpretation of the red-shift observed in their spectra.

I think, however, that we shall have to accept the expansion. My reason is that it now seems possible to calculate the cosmical constant  $\lambda$  by pure physical theory. The value is the same as that given by the recession of the nebulae, so that there is full confirmation.

I have been tracing the effects of the cosmical constant in the behaviour of the great system of galaxies—phenomena on the grandest scale we

\* Friday evening discourse delivered at the Royal Institution on Jan 22

have yet imagined. Now I want to turn to the other end of the scale and look into the interior of the atom, where, I think, we shall find that the same cosmical constant turns up again. It is, in fact, the main key to the mystery of protons and electrons. I cannot go very far into this part of the theory, but I will try to show why I am convinced that the cosmical constant comes into the theory of the atom. I must premise one thing. It is well known that, in Einstein's theory, gravitation has an interpretation not only as a force but also as a geometrical property—a curvature—of space-time. So also the cosmical constant has an interpretation not only in terms of repulsive force but also as a measure of curvature. The constant  $\lambda$  is, in fact, precisely equal to  $1/R^2$ ,  $R$  being the radius of the world in the equilibrium (Einstein) state from which we suppose it to have started.

Length is necessarily relative. That is one of the results of Einstein's theory which has become almost a commonplace of physics, but it was a rather complicated kind of relativity that Einstein considered—relativity to the motion of our frame of reference. I am going to refer to another much more elementary relativity of length, namely, that length always implies comparison with a standard of length. It is only the ratio of lengths that enters into our experience. Suppose that every length and every distance in the universe were suddenly to be doubled, nothing would seem altered. I do not think we could attach any meaning to the change. Intrinsically, Brobdingnag and Lilliput are precisely the same, it needs an intruding Gulliver—an extraneous standard of length—to make them appear different.

Now, it is commonly stated in physics that all normal hydrogen atoms have the same size, or have the same spread of electric charge. We have a very fundamental equation (the wave equation) determining the spread, which is supposed to apply to any hydrogen atom and, of course, gives the same result for all. But what do we mean by their having the same size? Or it may be better to put the question negatively—What would it mean if we said that two hydrogen atoms were of different sizes, that is, similarly constructed but on different scales? It would be Brobdingnag and Lilliput over again. To give any meaning to the difference, we need a Gulliver. Now, the Gulliver of physics is always supposed to be a certain bar of metal called the International Metre. He is anything but a traveller, I think he has never been away from Paris. It was Prof Weyl who first directed attention to the very big hiatus involved, when we speak of a length such as the radius of a hydrogen atom being a certain fraction of the standard metre. We have, as it were, our Gulliver but have left out his travels. The travels are (as Weyl showed) the interesting part of the story, and are not to be glossed over as irrelevant.

Weyl went further and pointed out that there is a natural standard of comparison which is always on the spot, namely, the radius of curvature of the world *at that spot*. We can thus give a direct meaning to the statement that two hydrogen atoms in

any part of the universe have the same size, we mean that each of them is the same fraction of the radius of curvature of space-time at the place where it lies. The atom here is a particular fraction of the radius of curvature here, the atom on Sirius is the same fraction of the radius of curvature at Sirius. Whether the radius of curvature here is the same as at Sirius does not arise, and I do not think there is any meaning in trying to compare them.

The above definition of equality, and the use of Weyl's standard, may seem a dangerous innovation, but, indirectly, we have been using it all along, without knowing that we were doing so. Some years ago I pointed out that Einstein's law of gravitation can be stated in the form, "What we call a metre at any place and in any direction is a constant fraction of the radius of curvature of space-time for that place and direction." That is simply a translation of the law from symbols into words. The law is verified by observation, so that the statement gives us not only an ideal definition of the metre but also one which we know will accord with the reckoning of metres that is actually used. Thus, measurement in terms of the metre is equivalent to measurement in terms of the world radius, since the two standards are always in a constant ratio. Practically, it is more convenient to employ the metre, but in pursuing the theory we must go direct to the world radius, for obviously a particular bar of metal at Paris can have no fundamental status in physics and is altogether irrelevant to equations describing the mechanism of the atom. The world curvature, on the other hand, is on the spot and is directly reacting with the atom.

I now return to the wave equation which professes to determine how large an atom will be. That, as we have seen, means that it finds the ratio of the various intervals in the atom to the world radius there, so the world radius must come into the equation. But the world radius is the cosmical constant in another form. The cosmical constant has cropped up again inside the atom.

My task now was to spot the cosmical constant or the world radius in the current form of the wave equation, which is known by experiment to be substantially correct. It is very much disguised, because the current equation introduces the standard metre and all sorts of irrelevancies. But one knows the sort of effect that curvature can have, and the way it will appear in the equation is pretty well dictated by the quantum laws, which make a speciality of the properties of 'closed circuits' such as are introduced by curved space. I think I succeeded, and I arrived at the identification

$$mc^2/e^2 = \sqrt{N/R}$$

The left side is a term in the current wave equation, and its value is known experimentally. The right side is the way that we write it now that we have penetrated its disguise.  $R$  is the Einstein radius of the world, equal to the inverse square root of the cosmical constant,  $N$  is the number of electrons (or protons) in the universe.

This additional equation, combined with other equations already known, gives all the information required. We deduce, for example, that the number of electrons in the universe is  $1.29 \times 10^{79}$ , and that the original radius of the universe, before it started to expand, was 1070 million light-years. Most important of all, we find that the consequent rate of expansion of the universe is 528 km per sec per megaparsec distance. The observational determinations from the recession of the spiral nebulae (which might be a little lower, since they include any countervailing gravitational attraction) range from 430 km to 550 km per sec per megaparsec. We can feel little doubt, therefore, that the observed motions of the nebulae are genuine and represent the expansion effect predicted by relativity. We must reconcile ourselves to this alarming rate of expansion, which plays havoc with older ideas as to the time-scale.

However interesting may be the application of this theory to the universe, the application to the interior of the atom seems likely to be still more fruitful. Now that we know the magnitude of the

radius of curvature, we can set aside the arbitrary metre and use this natural unit in our equations. The big uninformative coefficients disappear, and the equations are so much simplified that, I think, I have a fair idea of what they really mean and how they work. In particular, the relation of the proton to the electron is now apparent, and the theoretical ratio of their masses is found to be  $1847.6$ , this is certainly very near to the observed value.

I do not want to stress too much the accuracy or finality of these first results. I cannot see how anything can possibly be wrong with them, but then one never does see these faults until some new circumstance arises or some ingenious person comes forward to show us how blind we have been. At least, a way of progress has been found. I think that some day, when electrons and protons have come to order, we shall look back and see that the key to the mystery was lying somewhere in intergalactic space and was picked up by astronomers who measured the velocities and distances of nebulae ten million light-years away.

### Goethe as Biologist

By Prof. F. J. COLE, F.R.S., University of Reading

THE celebration of the centenary of the death of Goethe, which occurred on March 22, 1832, has evoked a series of works dealing with the activities of that unique genius. Among them is a critical biography by Prof. J. G. Robertson, the eminent authority on the life and works of Goethe.\* This treatise is outside the scope, but not indeed outside the interests, of a scientific journal such as NATURE, except for the fact that it includes an enlightening chapter on Goethe's contributions to science. As a matter of personal history Prof. Robertson can scarcely be expected to take other than a detached view of Goethe's scientific achievements, and it is therefore not surprising to find him stating that "we look to Goethe, not for scientific discovery, an activity with which many other minds were as able—and perhaps better able—to cope successfully, but to more precious discoveries in the realm of the spirit and the imagination. May we not thus cherish something of a grudge that his immersion in scientific pursuits took up so very large a share in his life?" Prof. Robertson, however, would be the first to admit that Goethe himself would have indignantly denounced such an attitude, which strikes at the root of one of his characteristic speculations as to the nature of creative art. To him the living organism was a work of art which only an artist could be expected to comprehend. Further, it is precisely those attributes of the spirit and imagination which give to his scientific work the qualities we all find so fascinating.

It was in an essay written in 1795, but not published until 1820, that Goethe focused attention on the unity of plan or organic constant which was

supposed to underlie the organisation of all living beings. Since there was only one plan or idea, the world was regarded as something akin to a vast musical symposium, in which the poverty of a solitary theme was enriched by an endless and expanding series of variations. All forms were interpreted in terms of this ideal simulacrum,† and even man himself must be studied comparatively, working downwards from higher to lower types. This is the so-called law of reduction, or, to paraphrase the words of Geoffroy—there is but a single intangible being which becomes patent to our senses under diverse forms. Goethe was, of course, not the first to adopt such an attitude, but he was the first to convert it into an ordered scientific theory. The plan was put into operation or integrated by a controlling dynamic principle or *Bildungstrieb*. It is obvious at the outset that the theory is a scheme of development and not a principle of evolution, and, further, that its working out must depend on the institution of a system of homologies. There is one attractive feature in this point of view. However wrong it may be, it attempts to provide a common explanation of organic phenomena, and does not countenance the artificial separation of animals and plants.

Goethe's eager pursuit of homologies, of uniformity in diversity, was bound to lead to the conception that there was only one animal. Not merely was there a single animal type, but the integration of the type itself was effected by linking up into a series a number of similar, complete, subordinate entities like a string of beads. He extended the same speculation to plants, and interpreted, as others had done before him, the

\* "The Life and Work of Goethe, 1749–1832." By Prof. J. G. Robertson. Pp. xii+350+8 plates. (London: George Routledge and Sons, Ltd., 1932.) 12s. 6d. net.

† Goethe would not have approved this term, but the 'reality' of the idea is that of a mental abstraction projected on to paper like Owen's Archetype.

leaves, sepals, petals, stamens, and pistils as variants of a common structure, just as the skull of the animal represented the efflorescence of the vertebral column. Leaf and vertebra were the elemental structures of animal and plant. He was not unmindful of the fact that modifications of the plan cannot be introduced without affecting the status of the whole, and his law of balance, that "in order to spend on one side, Nature is forced to economise on the other side", is closely related to the famous deduction made by Cuvier in 1812 of the law of correlation, which was exploited with such dramatic effect by himself and later comparative anatomists. Goethe was not the only biologist to become obsessed with this idealistic morphology. Even Johannes Müller himself embodied it in his "Inaugural Dissertation"—a lapse which this sensitive man lamented so deeply in later years that he bought up and destroyed all copies of the offending thesis.

It is not difficult to understand why Haeckel should have been led to credit Goethe with a share in the triumph of evolution, and to regard him as a forerunner of Darwin. Both Haeckel and Goethe were convinced upholders of the comparative method, and Haeckel was powerfully influenced by the genius of the poet. In Goethe's work on the metamorphosis of plants published in 1790, which is considered to be the beginning of speculative morphology,\* there are passages which give some support to the claim. Everything depends on his interpretation of what is called 'metamorphosis'. Is it an objective historical reality, as any principle of organic evolution is considered to be, or is it a philosophical conception expressing nothing more than the realisation of a generalised subjective plan or idea, which itself is not inconsistent with Nature philosophy and special creation? He hesitates between these alternatives, nor does it appear that they were ever sharply contrasted in his own mind, and he has no consistent views with regard to either. His contemporaries included him among the Nature philosophers, and Goethe, who did not hesitate to express the liveliest dissatisfaction when his scientific works were misunderstood, never thought it worth while to correct them. In his later writings, however, he appears at times to have a clearer perception of the evolutionary alternative, but again, at the close of his life, in 1830, he was supporting Geoffroy in his contest with Cuvier, which shows how far he was from comprehending the historical implications of evolution. There is no evidence that he ever specifically discussed the problem of species, regarding such speculations as "a useless occupation which we may well leave to those who are fond of busying themselves with insoluble problems" (Robertson).

The main point of contact between Goethe and Haeckel lies, however, in the fact that the evolutionist, like the Nature philosopher, also expects to find uniformity in diversity, but he only looks for it where it may reasonably be expected to

exist, nor is he in any way constrained to mould the facts or stretch the argument in those cases where the quest has been unsuccessful. Failure must not only be expected but also accepted, since it does not affect the essential truth of the principle of evolution, but merely its mode of operation. Whilst, therefore, Goethe's methods were up to a point those approved by Haeckel and the evolutionists, he goes, and must go, considerably beyond the permitted limits of scientific induction. Having assumed the existence of a single animal type, it follows that, unless evidence for such a type be forthcoming, every species must be manipulated to conform to it. Such was the error of Goethe and his successors the Nature philosophers, and it must be held definitely to exclude them from the evolutionary circle, although Goethe himself was never guilty of the ludicrous extravagances of his disciples. In one cardinal respect, however, he was remarkably sound. He saw that purely morphological speculation was as dust and ashes in the mouth compared with the vision of the form and activities of an animal as a living organic whole. Or in other words, the *complete* organism only can give us understanding of its inner meaning or idea.

The attitude adopted by Goethe towards the question of animal relationships may be profitably explored by a comparison of his two researches on the intermaxillary bone and the vertebral theory of the skull. The former was written up in 1784 and bears the date of 1786 (*sic*),† but it was not published until 1831, although an abstract without illustrations appeared in 1817. The latter paper was drafted and communicated to friends in 1790, but was actually published in 1820, this belated publication being responsible for the priority dispute with Oken. The alleged absence of the premaxilla in man was considered to separate him definitely from the apes—a conclusion which ignored the fact that if the bone is absent in man it is also wanting in the higher apes. Goethe sought to establish its presence in man by methods not dissimilar from those of the modern comparative anatomist. He examined its condition in a number of mammals, noted variations in its state of development and correlated them with feeding habits, investigated aberrant cases such as that of the elephant, and succeeded in finding the bone in some species in which it had not been described. Finally, by comparing human adult and foetal skulls, he demonstrated its presence in man ‡. He thus established the importance of embryology in the interpretation of adult structure. His work, in fact, is an admirable essay in comparative anatomy.

The research on the skull, however, belongs to another category. It has no concern with experience, but is an exploitation of the Idea. Whether the skull is vertebral in nature or not, cannot be tested by observation. If, however, we concede the point, the skull may have been formed on the

\* Goethe introduced the term morphology in 1817, but his definition of it is not retained in modern usage.

† This date is usually but erroneously quoted as the date of publication.

‡ The bone was not first discovered in man by Goethe. Vesalius and Fallopius saw indications of it in 1543 and 1561, and Vicq D'Azyr described it in the human foetus in 1780-84.

vertebral pattern as the result of the operation of a creative force working according to plan, or it may have been produced from modified vertebrae by a process of evolution. In either event, the investigator is confronted with an abstraction beyond the means of verification. It is otherwise with the case of the intermaxillary bone. Here the 'metamorphosis' may be tested and observed in all its stages, and an evolutionary conclusion becomes not only possible but almost inevitable. But how did Goethe regard these two problems? To him their implications and significance were identical, and the only inference he drew from both of them was a confirmation of his theory of the common plan or idea. To such an outlook, deduction and induction are indistinguishable. Had the history of the intermaxillary bone suggested to his mind any conception of genetic relationships, he would surely have said so. Goethe

therefore was a forerunner of Darwin only in the sense that before the historical continuity of species could be established it was necessary to formulate a doctrine of homologies, and in this important work Goethe played a leading part.

Not until the end of his life did Goethe exercise any appreciable influence on the biological thought of the period. This was due partly to delays in publication, but particularly to the imaginative and romantic character of his work—a quality rarely grateful to the academic mind. At first his influence was almost wholly reactionary, but the eclipse of Nature philosophy purged his writings of their ephemeral content and made it possible to form a sound judgment of the residue, with results that have only become evident in modern times. That his biological work will always command the respect and admiration of scientific men is a conclusion to which all his critics would assent.

### Goethe's Reflections on Nature

WE reproduce below the translation of Goethe's reflections on Nature by T. H. Huxley, which was published as an introductory article to the first number of *NATURE*, dated Nov. 4, 1869. As originally printed, a casual reader might easily conclude that this lyrical composition was the work of Huxley himself, and in a letter to Dohrn, written shortly afterwards, he says "It astonishes the British Philistines not a little. When they began to read it they thought it was mine, and that I had suddenly gone mad." Darwin himself was stirred to admiration, and wrote to Hooker as follows: "Lord, what a rhapsody that was of Goethe, but how well translated, it seemed to me, as I told Huxley, as if written by the maddest English scholar. It is poetry, and can I say anything more severe?" Huxley added to his translation some comments upon Goethe's "wonderful rhapsody on Nature which has been a delight to me from my youth up", and he referred to it in an article entitled "Past and Present", contributed by him to the first issue of our fifty-first volume, on Nov. 1, 1894. In a footnote to this article, Huxley said: "A better translation than mine and an interesting account of the very curious obscurity which hangs about the parentage of *Die Natur* are to be found in Mr. J. Bailey Saunders' recently published 'Goethe's Aphorisms and Reflections'."

#### NATURE APHORISMS BY GOETHE \*

NATURE! We are surrounded and embraced by her powerless to separate ourselves from her, and powerless to penetrate beyond her.

Without asking, or warning, she snatches us up into her circling dance, and whirls us on until we are tired and drop from her arms.

She is ever shaping new forms what is, has never yet been, what has been, comes not again. Everything is new, and yet nought but the old.

We live in her midst and know her not. She is incessantly speaking to us, but betrays not her secret. We constantly act upon her, and yet have no power over her.

\* From *NATURE*, Nov. 4, 1869.

The one thing she seems to aim at is Individuality, yet she cares nothing for individuals. She is always building up and destroying, but her workshop is inaccessible.

Her life is in her children, but where is the mother? She is the only artist, working up the most uniform material into utter opposites, arriving, without a trace of effort, at perfection, at the most exact precision, though always veiled under a certain softness.

Each of her works has an essence of its own, each of her phenomena a special characterisation and yet their diversity is in unity.

She performs a play, we know not whether she sees it herself, and yet she acts for us, the lookers-on.

Incessant life, development, and movement are in her, but she advances not. She changes for ever and ever, and rests not a moment. Quietude is inconceivable to her, and she has laid her curse upon rest. She is firm. Her steps are measured, her exceptions rare, her laws unchangeable.

She has always thought and always thinks, though not as a man, but as Nature. She broods over an all-comprehending idea, which no searching can find out.

Mankind dwell in her and she in them. With all men she plays a game for love, and rejoices the more they win. With many, her moves are so hidden, that the game is over before they know it.

That which is most unnatural is still Nature, the stupidest philistinism has a touch of her genius. Whoso cannot see her everywhere, sees her nowhere rightly.

She loves herself, and her innumerable eyes and affections are fixed upon herself. She has divided herself that she may be her own delight. She causes an endless succession of new capacities for enjoyment to spring up, that her insatiable sympathy may be assuaged.

She rejoices in illusion. Whoso destroys it in himself and others, him she punishes with the sternest tyranny. Whoso follows her in faith, him she takes as a child to her bosom.

Her children are numberless. To none is she altogether miserly, but she has her favourites, on whom she squanders much, and for whom she makes great sacrifices. Over greatness she spreads her shield.

She tosses her creatures out of nothingness, and tells them not whence they came, nor whither they go. It is their business to run, she knows the road.

Her mechanism has few springs—but they never wear out, are always active and manifold

The spectacle of Nature is always new, for she is always renewing the spectators Life is her most exquisite invention, and death is her expert contrivance to get plenty of life

She wraps man in darkness, and makes him for ever long for light She creates him dependent upon the earth, dull and heavy, and yet is always shaking him until he attempts to soar above it

She creates needs because she loves action Wondrous that she produces all this action so easily Every need is a benefit, swiftly satisfied, swiftly renewed—Every fresh want is a new source of pleasure, but she soon reaches an equilibrium

Every instant she commences an immense journey, and every instant she has reached her goal

She is vanity of vanities, but not to us, to whom she has made herself of the greatest importance She allows every child to play tricks with her, every fool to have judgment upon her, thousands to walk stupidly over her and see nothing, and takes her pleasure and finds her account in them all

We obey her laws even when we rebel against them, we work with her even when we desire to work against her

She makes every gift a benefit by causing us to want it She delays, that we may desire her, she hastens, that we may not weary of her

She has neither language nor discourse, but she creates tongues and hearts, by which she feels and speaks

Her crown is love Through love alone dare we come near her She separates all existences, and all tend to intermingle She has isolated all things in order that all may approach one another She holds a couple of draughts from the cup of love to be fair payment for the pains of a lifetime

She is all things She rewards herself and punishes herself, is her own joy and her own misery She is rough and tender, lovely and hateful, powerless and omnipotent She is an eternal present Past and future are unknown to her The present is her eternity She is beneficent I praise her and all her works She is silent and wise

No explanation is wrung from her, no present won from her, which she does not give freely She is cunning, but for good ends, and it is best not to notice her tricks

She is complete, but never finished As she works now, so can she always work Everyone sees her in his own fashion She hides under a thousand names and phrases, and is always the same She has brought me here and will also lead me away I trust her She may scold me, but she will not hate her work It was not I who spoke of her No! What is false and what is true, she has spoken it all The fault, the merit, is all hers

## Obituary

DR G CLARIDGE DRUCE, FRS

THE death on Feb 29, at Oxford, of Dr George Claridge Druce removes not only the best-known student of our British flora but also a remarkable personality The charming story of his early life, which he has given us in the introduction to his "Flora of Buckinghamshire", shows how circumstances worked to shape his life and mould his character He was born on May 23, 1850 The *res angustae* of his childhood threw him into the arms of Nature for his diversion, and his playthings were the wild flowers around the Northamptonshire village where his widowed mother had made her home He tells how, by the lack of foresight of his guardian, he was debarred from a public school education, but the individuality which characterised his work through life, his independence, his undaunted persistence in arriving where others would have fallen short, may perhaps be traced to the less rigid training of his early years In the woodlands near his home he studied the insect life as well as the plants, and by the age of fourteen had made a very representative collection of the local Lepidoptera, pupæ were dug for and larvæ bred, and plants were fixed in the memory by making carbon impressions of the leaves Holidays spent in different localities in Bedfordshire on the greensand and chalk enlarged his knowledge of the flora and insect life

At fifteen Druce was apprenticed to a large wholesale and retail chemist's business in Northampton, and two years later became acting-manager The long business hours left little time for field-work, much of which was done by rising at 5.30 or 6 A.M. During the years that followed, without tutorial aid, he studied for and passed

with honours the examinations for a pharmaceutical chemist A herbarium was indicated as part of the equipment of a pharmacist, in 1873 one was begun, and in the first year he collected about 750 species He was now definitely working on the preparation of a "Flora of Northamptonshire", which was printed in 1879 in the *Journal of the Northamptonshire Natural History Society*, of which he was one of the founders and had also acted as honorary secretary and president His last important piece of work was a much enlarged and fuller "Flora" of his native county, published in 1930

In 1879 Druce bought, with his savings, the pharmacy in High Street, Oxford, where he remained in business for the rest of his life Prominent landmarks of subsequent years are the "Floras" of the Thames valley counties, at which he worked successively—Oxfordshire (1886), Berkshire (1897), and Buckinghamshire (1926) But the preparation of these county floras by no means represented the sum of his botanical work No man had so intimate a personal knowledge of the British flora, which had been gained by frequent excursions to all parts of the country The fact that a 'new' plant had been reported in Skye or some other locality, near or remote, was enough to send him hot-foot in search of it, and the Annual Reports of the Botanical Society and Exchange Club, which, as secretary, he has drawn up since 1904, are replete with new records and critical notes on British plants by himself and other botanists The Botanical Society of the British Isles, which Druce started in 1908 as an appendage to the Exchange Club to enlist the help of well-wishers as well as of active workers, did

much to popularise British botany. The Report for 1930, issued last August, after his eightieth birthday, is a testimony to his remarkable energy and virility, recording, as it does, excursions to widely distant parts of the British Isles and a visit to Cyprus.

Not the least interesting fact in Druce's career was his association with the University of the city in which he had his business. Oxford accepted him and honoured him. A botanist visiting a University official (not on the science side) was asked, "You know *our* botanist—Mr. Druce?" In 1895 he was appointed Curator of the Fielding Herbarium and attached to Magdalen College with an honorary M.A. degree. Many years later he was awarded the D.Sc. In association with the professor of botany, Dr. S. H. Vines, he published accounts of two of the historic Oxford Herbaria, the Dillenian in 1907, and the Morisonian in 1919.

Druce's botanical travels were not confined to the British Isles. He had a good personal acquaintance with the European flora, especially of the Mediterranean area. In 1914 he was in Australia with the British Association, and he had also visited South America.

Druce was a good citizen—a member of the City Council, sheriff (1897), and mayor (1900). He had also served as president of the British Pharmaceutical Conference. Writers in the public press have borne testimony to his unsparing readiness to advise and help students of the British flora, however humble, and his wide circle of friends and the remarkable response to the memorial presented on his eightieth birthday testified to the esteem and affection in which he was held. Druce had his foibles. He dearly loved a title. He did not

scruple to strain a point to enable him to write *mihi* after a plant-name. His handwriting was execrable. A regrettable and life-long quarrel arose partly from an honest but unsuccessful attempt by an editor to transliterate a botanical communication from him. He had the true collector's spirit—the impulse to get in first.

A remarkable man, Druce has made a noteworthy contribution to British botany by his personal influence, by his published floristic works, and by the rich herbarium and library which he has left with his house and an endowment as a Botanical Institute for the use of botanists. His election to the fellowship of the Royal Society in 1927 was a graceful and appropriate recognition of his work.

A. B. RENDLE

WE regret to announce the following deaths

Prof. Alexander Dougall Blackader, emeritus professor of therapeutics and pharmacology in McGill University, Montreal, past president of the Canadian Medical Association, on March 14, aged eighty-five years.

Prof. D. H. Marshall, emeritus professor of mathematics and physics in Queen's University, Kingston, Ontario, on March 14, aged eighty-four years.

Prof. Giuseppe Martinelli, assistant secretary of the Pontifical Academy of Science, Vatican City, and assistant in the Royal Central Office of Meteorology and Geophysics, Rome, aged fifty-four years.

Prof. Henry J. Priestley, professor of mathematics in the University of Queensland, Brisbane, on Feb. 26, aged forty-eight years.

## News and Views

### John Hunter

MR. WILFRED TROTTER gave the Hunterian Oration at the Royal College of Surgeons on Feb. 15, and his oration stands out among the long series as remarkable for the amount of interesting chronological analogies and psychological questioning which he has managed to compress into twelve pages. His best point is bringing out the fact that Hunter achieved his results, making modern, in fact, the practice of surgery, at a time when most of the discoveries of science on which we now rely had still to come. During his life, 1728–93, the biologist could look for little help from the sciences of the inorganic. The work of Cavendish, Priestley, Galvani, Volta, and Lavoisier was still to come. He would have had to wait ten years for Priestley's discovery of oxygen in 1775, and more than sixty for Wohler's synthesis of urea and the foundation of biochemistry in 1828. Joule's mechanical equivalent of heat came nearly eighty years later. Joseph Jackson Lister's compound microscope was sixty years ahead, and Lister's greater son did not make clear the nature of wound infections until just a century after Hunter. All this

enhances enormously the merit of Hunter. He stands out the more clearly as one of those successful practitioners of science, who by untiring work, scrupulous accuracy, and perfect devotion to truth have worked marvels.

### Purpose of Commemorations

MR. TROTTER's remarks, however, on the practice of commemorating the eminent dead, seem to us somewhat to obscure the main point of such commemorations by the curious psychological data which he suggests. There is a Freudian touch about it which, true as it may be genetically, is ontologically now invalid. Because primitive man did sacrifices to appease the 'manes' of the departed and was in actual fear of his ghost, it does not follow that there is any such dread of the reappearance of Hunter. His ghost would, we are sure, have been most cordially welcomed at Mr. Trotter's discourse on Feb. 15. Admiration as well as perfect love casteth out fear. Nor does the ancient practice of partaking of the bodily remains of the dead hero now prompt us to any really analogous act. We commemorate to

instruct ourselves, to inspire others to act in a way similar to that of the men we revere, perhaps, most of all, to impress the fact of the debt of the living to the past. The continuity of primitive savage instincts in the civilised is a plausible but misleading fallacy in psycho-analysis, and at the best a grave exaggeration. However, in Mr Trotter's address these allusions only add a quaint flavour of romance. We sympathise with him in his hope that the truly great may be recognised in their lifetime, but we would not have this at the cost of diminishing the respect and remembrance of them after their death. The growth of the latter practice is one of the best features of the age, and offers hope that we may be able to combine our vertiginous progress with the continuity of order.

### Third Pedler Lecture of the Chemical Society

PROF. L. RUZICKA, of Zurich, delivered the third Pedler Lecture to the Chemical Society on March 10, his subject being "The Life and Work of Otto Wallach." Prof. Wallach, whose outstanding contribution to organic chemistry was his pioneer work on the terpene series, was born in Königsberg on March 27, 1847, the son of a Prussian official. His early education was on classical lines, and in addition he had a lifelong interest in the contemplation of art. In 1867 he began his chemical studies in Göttingen under the direction of Wohler and his assistants, Fittig and Hubner. In the atmosphere of industry which was there cultivated, Wallach obtained his doctor's degree after five semesters of study, his dissertation dealing with position isomerism in the toluene series. After a short period in Berlin as assistant to Wichehauser, he accepted in 1870 an assistantship at Bonn, offered to him by Kekulé. The period at Bonn, which lasted for nineteen years, was interrupted for a short time when he went to Berlin as the sole chemist to a newly founded enterprise which later developed under the name "Aktiengesellschaft für Anilinfabrikation" (Agfa). In 1889 Wallach was called to Göttingen as successor to Victor Meyer, and retained the direction of the Chemical Institute until 1915. In 1908 he was elected an honorary member of the Chemical Society, and in 1909 received an honorary doctorate of the University of Manchester. The Nobel prize for chemistry was awarded to him in 1910. Wallach died on Feb. 26, 1931, having made such contribution to organic chemistry that any attempt to picture the science with Wallach's work removed would unmistakably disclose a severe gap.

### Wallach's Chemical Investigations

PROF. RUZICKA gave a brief sketch of the principal investigations conducted by Wallach in the domain of terpene chemistry. The work originated in a study of several samples of essential oils which had been kept untouched for fifteen years in a cupboard in Kekulé's private laboratory. It soon became evident that "a great many terpenes formerly designated differently and of supposedly varying constitution are undoubtedly identical." In the first stages several simple reagents were caused to act on the separate

fractions of natural terpene mixtures with the view of the separation of crystalline reaction products. In three years Wallach was able to list eight terpenes which obviously differed from one another, each being characterised without ambiguity: pinene, camphene, limonene, dipentene, sylvestrene, terpinolene, terpinene, and phellandrene. Later it appeared that dipentene is *dl*-limonene, and that pinene, terpinene, and phellandrene are mixtures of  $\alpha$ - and  $\beta$ -compounds; moreover, it is now known that sylvestrene does not occur in Nature. Wallach also investigated oxygenated terpene derivatives and the sesquiterpenes, particularly cadinene and caryophyllene. After characterisation of the individual terpenes, he considered the elucidation of their innumerable mutual relations to be more important than the determination of their constitution. The real harvest from the persistent work of Wallach was reaped in 1895, when, with a single stroke, the structure of an entire series of terpene compounds was elucidated. With the end, about this time, of the heroic period in terpene chemistry, Wallach ceased to play the part of pioneer. Of his later work, Prof. Ruzicka referred to that on bicyclic representatives of the terpene series, and that concerned with simple alicyclic compounds.

### Early History of Magnetism

At a meeting of the Newcomen Society held at the British Industries Fair, Birmingham, on March 2, Dr. J. B. Kramer read a paper on "The Early History of Magnetism", in which he discussed the various accounts of the first discovery of a magnet, and the development of the science of magnetism down to A.D. 1600. His remarks were divided into five sections, the first dealing with the discovery of magnetism up to and including the writings of Lucretius, about 95-52 B.C., the second with the interpretations and first applications of magnetism up to the thirteenth century, the third with the experimental researches of Peter Peregrinus of Maricourt, A.D. 1269, the fourth with the magnetic compass, between the thirteenth and sixteenth centuries, and the last with the discovery of terrestrial magnetism by Gilbert, and with Gilbert's book, "De Magnete."

### Discovery of Magnetic Properties

For the claim that is sometimes made that the magnet was first known to the Chinese, Dr. Kramer finds no support, but after examining the works of Aristotle and others, he comes to the conclusion that the magnet was discovered accidentally by one of the Grecian tribes who originally inhabited Thessaly and were called Magnetes. The discovery was made in one of the settlements in Asia Minor, in the Province of Lydia, about 600 B.C. That magnets attract through a distance, that they induce magnetism in iron, and that they repel as well as attract, are mentioned by Lucretius. Who made the great discovery that if allowed to move freely a magnet pointed north and south is not known, but Peter Peregrinus describes the dual polarity of magnets. The work of Gilbert was based on 199 'magnetical

experiments', and his greatest original contribution to science was his magnificent discovery and proof that the earth is a colossal natural magnet in itself. Dr Kramer's paper contains many extracts from the various writers on magnetism, and should prove of wide interest.

#### Goethe's Scientific Works

A SPECIAL issue of the Berlin journal, *Forschungen und Fortschritte*, dated March 1932, includes thirty-nine pages devoted to a series of articles by more than thirty authorities dealing chiefly with Goethe's influence as a man of science. The subjects covered include mathematics, the theory of colours and optics, chemistry, geology, meteorology, botany, zoology, and anatomy, together with an appreciation of the Goethe Museum at Frankfurt. In the restricted space at the disposal of each author, it has only been possible to deal very briefly with what are often abstruse and involved matters of history, but, nevertheless, these articles should prove a very useful guide to those who propose to take up the study of Goethe's scientific works. The modern critic of Goethe's central idea of the unity of plan has little to add to Schiller's acute observation of 1794, quoted by Prof O Abel—"Das ist keine Erfahrung, das ist eine Idee", and Goethe's response—"Das kann mir sehr lieb sein, dass ich Ideen habe, ohne es zu wissen, und sie sogar mit eigenen Augen sehe", is an admirable epitome of his own attitude towards the central idea.

#### Source of 'Nagana' in South Africa

DR E WARREN, director of the Natal Museum, has reported, according to a message in the *Times* of March 10, that experiments carried out by Mr Davidson, an independent naturalist, "completely destroy the theory at present accepted about the reservoir of infection from which the tsetse fly transmits the widespread cattle disease known as Nagana". It is generally accepted—and has, in fact, been repeatedly proved—that the blood of game animals harbours trypanosomes which, when conveyed to domestic animals by the tsetse fly, give rise to the serious and often fatal diseases which are grouped under the term 'nagana'. Mr Davidson now claims to have shown that the trypanosome responsible is derived from the latex of certain plants "on which the tsetse fly normally feeds". Further information on these observations (which appear to have satisfied Dr Warren, by whom they have been "carefully checked") will be awaited with much interest. It is well known that leptomonad-like flagellates are common in the latex of *Euphorbia* and other plants, being transmitted from one plant to another by certain plant-sucking bugs, but no evidence has as yet been published that these organisms can cause disease in vertebrates, and up to the present time no trypanosome has ever been discovered in a plant. The tsetse fly has occasionally been observed to plunge its proboscis into certain fruits, but in the past it has seemed very doubtful if these constitute a regular source of food supply.

#### Chester Roman Amphitheatre Appeal

DETERMINED efforts are to be made to save the Roman amphitheatre at Chester, which is threatened by the proposal to construct a by-pass road that, on the lines contemplated at present, would pass through the centre of the arena. The Council of the Chester and North Wales Archaeological Society has issued a statement in which it is pointed out that even if the road could be constructed without damage to the remains, which is doubtful, it would put excavation in the future out of the question, while it is inevitable that the northern area adjoining the road would be developed for building purposes, and also made inaccessible. The Office of Works, which has been approached in the matter, views with approval the scheme to save the amphitheatre, which is the most considerable in Great Britain. The Office of Works would itself undertake the cost of excavation and be responsible for the future maintenance of the monument if the site was placed in its keeping. The cost of diverting the by-pass road to avoid the amphitheatre is estimated at a sum of £8000. The Council of the Archaeological Society, therefore, appeals to the people of Chester, and of Great Britain, for a sum sufficient to enable this monument to be preserved. A stay of three months has been granted to afford an opportunity for the amount required to be raised.

#### Metallurgical Literature

THE annual general meeting of the Institute of Metals was held on March 9 and 10, and the incoming president, Sir Henry Fowler, delivered his address on the first day. Referring to the literature of metallurgy forty years ago, Sir Henry remarked that it was very meagre in Great Britain, especially as regards non-ferrous metals, and that possibly this lack was in part responsible for the formation of the Institute of Metals, for among its original objects was the publication of a journal containing original papers and abstracts. Abstracts appeared for the first time in the second volume of the *Journal* of the Institute, occupying 41 pages. In the last issue of the *Journal* in which they were incorporated, they occupied (with index) 436 pages. Now that the *Journal* is being published monthly, it is hoped that abstracts will be available within six weeks of the original publication of important papers. Sir Henry stated that more than a thousand periodicals, in about twenty languages, are searched systematically by a band of more than thirty qualified abstractors, who provided in the past twelve months more than four thousand abstracts. The magnitude of this undertaking is probably unique as the work of a single institution.

#### Practical Applications of Fundamental Research

SIR HENRY FOWLER went on to speak of the importance of fundamental research and of the 'marrying-up' of research with its practical applications. There is nowadays unquestionably much better understanding between the research worker in metallurgy and the practical engineer, due to the

increased facilities for metallurgical education and to the growing importance of metallurgy. Difficulties are still met, however, when the research worker neglects to express himself simply and intelligibly, or the practical man may be unduly conservative as regards new ideas. Sir Henry quoted one example from his own experience in which prejudice was likely to obstruct the application of research in practice. In 1922 he heard incidentally that a small percentage of copper increased the corrosion-resisting properties of steel. Owing to the story, apparently, that if a puddler wished to get a fellow-worker into trouble, he threw a penny into the puddling furnace, it was difficult to get the material made. Finally, Sir Robert Hadfield accepted the order for a small cast of 'copper-bearing steel'. The metal was required for the smoke-box and ash-pan plates of locomotives, and it took a further six or seven years to show that better results were obtained than with ordinary steel, thus emphasising another point, that the practical test of a discovery should be started as quickly as possible without awaiting its full development. The research associations are invaluable in bringing together those directly engaged in industry and those conducting research.

#### Land Utilisation Survey

THE Land Utilisation Survey of Britain organised by the London School of Economics and the Geographical Association, under the direction of Dr L. Dudley Stamp, reports considerable progress during its first year. A general report on the work is given in the *Bulletin of the Survey* for February. After fifteen months' work, four counties in England and one in Scotland are completely finished and another eight counties are on the verge of completion. Of the 22,000 quarter-sheets of the 6-inch map of Great Britain, 3670 have been finished. This is good progress, when it is borne in mind that the work had to be organised from the start in every county and is entirely on a voluntary basis. The completed sheets are being reduced to a 1-inch scale, and will then be printed in seven colours and issued by the Ordnance Survey. The numbering of these sheets will be on the basis of the popular edition of the 1-inch map. Sheet 114 (Windsor) is to be produced as an experimental sheet. While work is proceeding rapidly, in parts of the country, particularly in some of the counties of northern England, there are several areas in which little has yet been done. These blank areas include Gloucestershire, Essex, Huntingdon, several Welsh counties, the North Riding of Yorkshire, much of Northumberland, south-west Scotland, and large areas in the central and western Highlands. For these and other regions workers are still required.

#### Natural History in Church Records

It is strange from what odd quarters knowledge about the history of animal life may be gathered. This was apparently also the opinion of the vicar of Ridge, who refused permission to examine his parish books, on the ground that he found it difficult to conceive that payments for 'vermin' by parish

authorities could be of interest to anyone. Fortunately no other refusal was met by Charles Oldham, and the results of his searches amongst churchwardens' records in Hertfordshire are some odd contributions to the history of vermin (*Trans Hertfords Nat Hist Soc*, vol. 19, pt. 2, 1931). Sparrows, which had increased enormously in numbers because of the intensive cultivation of cereals, had a price upon their heads, and a record (Aldbury) of 1720 reads, "Pd for 6 Doz of Sparrows heads

1s", and yet, at the same period, others were deliberately encouraging sparrows to multiply by setting up for their use curious receptacles, 'sparrow-pots', from which the young sparrows were taken for food. The most telling of all the records are those relating to the prices paid for the destruction of polecats. In 1721, at Chipping Barnet, 4d was paid for two, in 1723 "for 4 Polecatt 4s" was paid at East Barnet, these records, giving the extreme range of prices, indicate a common and almost worthless creature, and contrast with the demand in Scotland, where at one stage the price of a furrier's dozen of polecats reached 45s. Long before that time, in the mid-nineteenth century, when fur value of the polecat had made its pelt desirable, the polecats of Hertfordshire had been exterminated as 'vermin'.

#### Irish Forests

THE opinion was widely held amongst Irish and English historians of the eighteenth and nineteenth centuries that Ireland was densely wooded down to the last five hundred years, and that the disappearance of the native forests was chiefly due to their exploitation by English adventurers, and the effects of the wars and disturbances during Elizabethan and Cromwellian times. According to A. C. Forbes in his paper on "Some Legendary and Historical References to Irish Forests and their Significance", read before the Royal Irish Academy on Feb. 22, a review of the various authors who were responsible for this conclusion has shown that none can be considered sufficiently acquainted with Ireland to have been an authority on the subject. State papers and other documents indicate that the arrival of the Normans in the twelfth century found Ireland much as it is to-day. A point of considerable interest is the exact position of forest land under the forest laws of the Normans. This forest land was the waste or unenclosed portion of the country, and had no direct connexion with woods or timber trees. Two Irish deafforestation charters of the thirteenth century are in existence, but no record can be found of any proceeding for creating a forest, and Mr Forbes advanced the theory that the wastes of both Ireland and England were normally afforested or subject to forest laws at a remote period, and that these laws were gradually removed by deafforestation, for which money payments were frequently made to the Crown. Manwood's "Lawes of the Forest" is a doubtful guide on this subject. A further point of interest is the existence of *Pinus sylvestris* in the Irish flora during the historic period. While the pine was a dominant species when the older

bogs were being laid down, its existence as an indigenous tree during the last thousand years is extremely doubtful

#### International Federation of Eugenic Organizations

WE have received a copy of the report of the ninth Conference of the International Federation of Eugenic Organizations, edited by the honorary administrative secretary, Mrs C B S Hodson, and published at 406 Fulham Road, London. The Conference met on Sept 11-15, 1930, at Farnham, Dorset, and Larmer Tree Grounds, Tolland Royal, Wilts. Associated public meetings were held at the Tithe Barn, Hinton St Mary, Dorset, at the invitation of Capt Pitt-Rivers. The first conference, under the chairmanship of Sir Arthur Keith, considered the standardisation of human measurements, with opening papers by Miss M L Tildesley on the physical and Miss B Schieffelin on the mental side. A conference on race crossing, with Dr Alfred Ploetz in the chair, received contributions from Dr Mjoen, Prof C G Seligman, Dr van Herwerden, Prof Ruggles Gates, Dr C B Davenport, and Prof Eugen Fischer. At another session international programmes for research in racial psychiatry were presented by Prof Rudin, and in racial psychology by Prof Seligman. An afternoon was devoted to heredity in man, with Prof Gates in the chair, and contributions by Dr P J Waardenburg, Dr C J Bond, Dr G P Frets, and Dr Heuyer. The report includes a summary of the discussion on each paper. The last part is devoted to general reports, including a brief statement from twelve countries regarding work on the eugenic or dysgenic effects of the War, and statements concerning recent eugenic work in Czechoslovakia, Finland, South Africa, Holland, Germany, and Austria. Dr H H Laughlin contributes a survey of eugenical work in the United States, Dr Mjoen one for Norway, and Dr Schrieber for France. This pamphlet of a hundred pages is a useful summary of work having anthropological and medical as well as eugenical aspects.

#### Wood Decay in Motor-Cars in the Tropics

THE practical importance of this question is indicated in a brief note in the *Philippine Journal of Science* (vol 46, No 2) by C J Humphrey, mycologist to the Bureau of Science, Manila. He states that the depreciation of imported automobiles in the tropics from this cause reaches "a staggering figure in proportion to the investment". Most of the cars in the Philippines are American, a few come from Europe, in either case the woods used in their construction are almost exclusively temperate zone species, selected for other properties than their durability. The decay sets in as the result of moisture in the wood, but, under the conditions in the tropics in the rainy season, water almost inevitably penetrates and, in the humid atmosphere, does not easily dry out again. The author states that "six months under test conditions very highly favourable for decay will destroy for all practical use nearly all the temperate zone woods now used in American or European-made cars". Up to the present three species of the higher fungi have been observed fruiting on the

rotting wood taken from cars, many more species probably contribute, but most of them are Hymenomycetes. The remedies for the trouble seem clear either the use of the heartwood of durable species of timber, presumably tropical species, by the manufacturer, or else the non-durable timbers must be adequately treated with a preservative.

#### Light upon Eggs

ANALYSIS shows that an inverse relation exists between the amount of daylight and the price of hens' eggs in successive months of the year. That in turn is correlated with the amount of food a hen may eat per day, so that the more light, the more food, and, other things being equal, the more eggs. Artificial lighting has been used on a large scale in the United States to shorten the long nights and induce hens to lay more, but it cannot be said to be a common practice in Britain. The results obtained by J W Rhys and Raymond T Parkhurst at the National Institute of Poultry Husbandry suggest, however, that its use might well be extended (*Bull* No 6). During the winter months the 120 pullets under lights laid 950 more eggs than an equal number without lights. For the 48 weeks of the test the lighted pen yielded 1086 eggs more than the unlighted pen. The lighted pullets laid an average of 173.5 eggs and the unlighted 161.0 eggs. Financially, the 'morning and evening lights' pen was most successful, the margin of profit over food and lighting costs being 11.58 pence a dozen eggs. Hens apparently give the best results under a 14-hour day.

#### The First 'Sky-scraper'

A POINT of considerable interest in the history of architecture has just been settled by a joint committee of the American Institute of Architects and the Illinois Society of Architects, which, having watched the demolition of the Home Insurance Building in Chicago, has declared it to be "the first tall structure of metal construction". The essential feature of a 'sky-scraper' is the metal skeleton, defined as "a type of construction in which a metal frame or cage, composed of girders, beams, and columns, supports all internal and external loads and carries all stresses to the foundations". Claims had been set up that the Tacoma Building of 1888 was the first tall metal skeleton building, but the committee states that in the Home Insurance Building there was "a complete skeleton framework, floor loads were carried by both interior and exterior columns, wall loads were transferred to columns, and columns were supported on independent footings". The Home Insurance Building was designed by William Le Baron Jenney and was erected in 1885. It has now been removed to make room for the gigantic Field Building in which 25,000 tons of steel will be used, but it will henceforth have its place in history as the first 'sky-scraper'.

#### Economic Uses of Beryllium

AMONG the rarer metals which are light in weight and therefore suggest themselves for employment in the aircraft and automobile industries, beryllium

stands out prominently. It is lighter than aluminium and has a much higher melting point than either aluminium or magnesium. In order to provide authoritative information about beryllium and the distribution of deposits of beryl—the only source of which adequate supplies are available—a useful little monograph has been prepared by the Mineral Resources Department of the Imperial Institute ("The Mineral Industry of the British Empire and Foreign Countries—Beryllium (Glucinum) and Beryl", 1931, pp. 26, price 6d). At present the metal is being produced commercially only in Germany and the United States. However, it is clear from the details provided that the British Empire is in a strong position to exploit its resources of beryl if adequate financial help can be found to follow up the preliminary work already accomplished in the field and laboratory. As is usual in this well-known series of monographs on economic minerals, there is a very full bibliography of the leading literature on the subjects dealt with.

#### National Institute of Industrial Psychology

THE eleventh annual report and the accounts for the year 1931 of the National Institute of Industrial Psychology have recently been published. The development of the Institute's work, in spite of the present financial crisis, continues satisfactorily. There is reported an increase of more than twenty-six per cent in the number of industrial and commercial firms for which the Institute has carried out investigations during the year, and an increase of nearly seventeen per cent in the number of cases examined for vocational guidance. The investigations are concerned with very varied activities, including work in gold mines, gasworks, a fish paste factory, and schools, and the problems investigated include equipment and lay-out of factories, as well as bonus schemes and staff selection. The very valuable work on vocational guidance continues, and while the Institute has acquired knowledge which enables it to advise young people on the choice of a career, yet it is recognised that much remains to be done—research work which will require several years for fruition is in progress. An allied problem, namely, occupational analysis, is also being continued, and studies being made of the abilities required for the various types of women's secretarial work and nursing. Other researches described include the nature and measurement of the mental abilities involved in factory assembly operations, motor drivers' tests, colour discrimination, and a very important investigation into the part played by rhythm in typewriting.

#### Health of the Army

THE health of the Army, at home and abroad, during 1930 is dealt with in the War Office Report recently issued (H.M. Stationery Office 2s 6d net). The ratio per 1000 of the strength of men admitted to hospital was 428.4, which is the lowest since the War, with the exception of 1928. Malaria caused 7365 admissions, venereal diseases, 6146, and inflammation of the tonsils, 5519. The principal causes

of invaliding from the Army were tuberculosis, 200 cases, and middle ear disease, 182 cases. Enteric fevers accounted for only 253 cases, of which 207 were in India. A single case of undulant fever is reported, an *abortus* infection at York. There were 534 cases of pneumonia, with a case mortality of 10.6 per cent. It is of interest that the pneumonia figures of forty years ago, selected at random, give a mortality figure of 12 per cent. Considering the less efficient nursing then available, this suggests that effective treatment of pneumonia has not materially advanced. Some details are given of researches carried out by officers of the Royal Army Medical Corps.

#### International Oceanography

PROF. R. DE BUEN, with the co-operation of leading international oceanographers, has compiled a valuable chronological list of voyages, long and short, made by vessels of all countries that have resulted in addition to oceanographical knowledge ("Lista cronológica de las campañas y navegaciones a las que se deben observaciones científicas de carácter oceanográfico". Memorias del Consejo Oceanográfico Ibero-Americano, No. 5, Madrid, 1930). The entries are arranged separately for each country, and indications are in most cases given of objects or results of the voyages, names of the leaders, and in some cases of scientific personnel. The compiler is open to receive corrections or additions to the list, which indeed appears to be very complete already. The earlier entries, which begin at the end of the fifteenth century, are for voyages primarily of a geographical nature. It is interesting to note that the British records, although not given in great detail, occupy nearly one-half the whole.

#### Agricultural History

THE Agricultural History Society of America wishes to secure as full bibliographical information as possible relating to books or essays on agricultural history for inclusion in its quarterly journal. Writers in the British Isles of essays on farming history and the history of rural life in all its phases, are therefore requested to forward details of their publications from time to time to the Associate Editor for Great Britain, Mr G. E. Fussell, at 47 Maple Street, London, W.1. Information regarding sections of scientific works which contain historical data, works of general history, or the history of specific trades or districts which contain sections dealing with agricultural history, might also be included. The quarterly journal of the Society, *Agricultural History*, is obtainable on payment of an annual subscription of three dollars, which should be forwarded to the Treasurer, Agricultural History Society, Room 304, 1358 B Street S.W., Washington, D.C., U.S.A.

#### The Remsen Memorial Collection

FORMER students in chemistry at Johns Hopkins University have organised the chemistry alumni of the University, with Dr. Harry N. Holmes, of Oberlin College, as president, and Dr. Lyman C. Newell, of Boston University, as secretary. Two meetings are held each year, ordinarily at the time of the meetings

of the American Chemical Society. At the last meeting it was decided to establish a Remsen Memorial Collection, and an appeal has been issued for early portraits of Dr Remsen, autographed letters on scientific subjects, and inscribed copies of the first, or an early, edition of his books, particularly books in a foreign language. Those who have memorabilia of this kind are requested to write to Dr Lyman C Newell, 688 Boylston Street, Boston, Mass.

#### Science in Poland

THE recent issue of vol 14 of "*Nauka Polska*" (Science and Letters in Poland), published by the Institute for the Promotion of Science and Letters in Poland (J Mianowski Funds, Warsaw, Staszic Palace 1931), is in line with the former volumes of this publication. It contains several original articles on the organisation and progress of science in Poland, as well as in Germany, Hungary, Czechoslovakia, Yugoslavia, Spain, and the United States. One article gives a review of the professorial members of Polish State universities. News of scientific activities and congresses both in Europe and America and reviews of new books are also included.

#### Science Abstracts

ALTHOUGH the volumes of *Science Abstracts* for 1931 are slightly less than those for the previous year, they include a larger number of abstracts: in physics 4365, of average length 0.254 page, and in electrical engineering 2697, of average length 0.262 page, there having been a marked decrease in the latter figure from last year. Both author and subject indexes are ample, and the two volumes continue to be indispensable for reference.

#### Announcements

At the annual general meeting of the Society of Public Analysts, held on March 4, the following were elected as officers for the year 1932: *President*, F W F Arnaud, *Hon. Treasurer*, E B Hughes, *Hon. Secretary*, G Roche Lynch.

At the annual general meeting of the Ray Society, held on March 10, the following officers were elected: *President*, Sir Sidney F Harmer, *Treasurer*, Sir David Prain, *Secretary*, Dr W T Calman. Sir J Arthur Thomson, Prof F E Weiss, and Mr E T Browne were elected new members of Council. In the report of the Council it was announced that the second volume of "*British Freshwater Copepoda*" is in the press and will be issued to the subscribers for 1932. It was also announced that Dr R W T Gunther has presented to the Society a portrait of his late uncle, Prof W C McIntosh. By permission of the President and Council of the Linnean Society, the portrait has been hung in the rooms of that Society.

IN connexion with the Thomas Gray Memorial Trust, the objects of which are the advancement of the science of navigation and the scientific and educational interests of the British mercantile marine, the Royal Society of Arts, which founded the trust

as a memorial to Thomas Gray, formerly assistant secretary to the Board of Trade (Marine Department), is again offering two prizes, each of the value of £100. One prize will be awarded for a valuable improvement in navigation proposed or invented in 1931 or 1932, and the other for an essay in connexion with navigation. Further particulars can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, London, W C 2.

A CATALOGUE (No 386) of nearly 3000 works relating to practically all branches of science, and a section on publications of the learned societies, has just been issued by Messrs W Heffer and Sons, Ltd. Petty Cury, Cambridge. It should be of interest to many readers.

AN item of particular interest to be included in the sale by auction by Messrs Sotheby and Co., 34 New Bond Street, W 1, on March 21 and the following day is Michael Faraday's electrical plate machine, made to his order by E G Wood of Cheapside, 1830, and exhibited at the Faraday Centenary Exhibition in September last. The sale will also comprise some letters of Charles Darwin and F T Buckland, and a collection illustrating savage art, from Africa, America, Oceania, and New Zealand.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A sub-librarian of the Literary and Philosophical Society, Newcastle-upon-Tyne—The Librarian, Literary and Philosophical Society, Newcastle-upon-Tyne (March 28). A woman lecturer in mathematics at the Bingley Training College—The Education Officer, County Hall, Wakefield (March 30). A principal of the Sunderland Municipal Technical College—The Chief Education Officer, 15 John Street, Sunderland (April 9). A pathologist, a radiologist, and a pharmacist at the Southend-on-Sea New General Hospital—The Secretary, New General Hospital, Southend-on-Sea (April 10). A woman lecturer in biology at the Edge Hill Training College, Liverpool—The Principal, Edge Hill Training College, Liverpool (April 29). A demonstrator in physiology and a part-time demonstrator in geology at the Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N W 1 (April 30). An assistant in the department of technology, City and Guilds of London Institute, for technical examination work, preferably with industrial knowledge, who has taught engineering or chemical subjects—The Superintendent, Department of Technology, City and Guilds of London Institute, 31 Brechin Place, S W 7. A director under the International Tin Research and Development Fund, to organise and direct international research and development, with the object of expanding the existing markets for tin, and of finding new uses for the metal—Sir John Campbell, 2 Richmond Terrace, London, S W 1. A professor of education and head of the men's training department of the University College of South Wales and Monmouthshire—The Registrar, University College of South Wales and Monmouthshire, Cardiff.

## Letters to the Editor

*[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]*

### The Expanding Universe

SIR ARTHUR EDDINGTON's recent work is of extraordinary interest, though there is some difficulty in getting hold of the right end of the stick. His recent Friday evening discourse at the Royal Institution appears elsewhere in this issue, however, and he also gave a rather fuller account of the work in his presidential address to the Physical Society last November.

It appears that in Einstein's theory of gravitation there are two terms in the expression for the gravitational action of one piece of matter on another. One term is the usual attraction, varying inversely with the square of the distance, while the other is a much smaller term, which can usually be neglected, representing an opposition force, or what can be spoken of as a repulsion, varying as the direct first power of the distance. This last only becomes important at enormous distances, but it is clear that at some distance or other it must first equilibrate the attraction, and then overpower it. It is obvious that the equilibrium thus obtainable between attraction and repulsion must be of the unstable kind, and it is supposed that if at one time the universe was in that critical condition of equilibrium as regards the matter on the outskirts of the whole system, the repulsion has now got the upper hand, so that any very distant matter is now receding, and receding with increasing speed as the distance increases. The result would seem to be that the matter outside the equilibrium boundary would gradually go away to infinity, while the matter inside that boundary would gradually contract.

I remember discussing with the late G. F. Fitzgerald how it came about that the forces between particles of matter were all of one sign, so that all matter attracted every other kind, and wondering whether there was any kind of matter that would be repelled, on the analogy of electric charges. Fitzgerald's view was that if there was any of the opposite kind of matter, it would have been repelled long ago, and could only be found at infinity. The Einstein theory, however, does not postulate another kind of matter, but another kind of force acting on all matter, so that it is all subject to both attraction and repulsion, though, in a reasonable neighbourhood, attraction is dominant.

Eddington, however, has further examined the repulsive term, or what he calls the cosmic constant, and finds that it, like the attractive one, can be related to a hypothetical curvature of space, so that what he speaks of as 'the expanding universe' does not signify merely an expansion of the universe of matter, but an expansion of the whole continuum in which the matter exists. This is a much more difficult idea than an effect on matter alone. It may be asked why the continuum should behave as a unit and all act together. The curvature of space is presumably due to the matter in it, the radius of curvature depending on the amount of matter. By certain equations, hitherto associated with atoms and electrons, Eddington considers that he has been able to calculate the radius of curvature of space, at least for the equilibrium condition, also the rate at which it should increase, and likewise the original amount of matter contained in space. He finds this amount equivalent to  $10^{79}$  atoms of hydrogen. If the amount of matter is gradually decreasing, owing

to its conversion into radiation, then it may be reasonable to suppose that the radius of curvature is increasing, unless indeed the radiation generated by the conversion can be considered gravitationally equivalent to the matter whence it was derived. For the radiation can never get out of the curved space, and so the content of that space may be considered constant, whichever form it happens to take.

There seem to be some discrepancies here, so that I feel sure I have not stated the position accurately, but in a subject of this novelty an old-fashioned physicist may be allowed to ask questions, and one way of asking a question is to make a statement and ask for a correction. One can but admire the heroic and apparently successful attempt of Sir Arthur Eddington to calculate a value not only for the things already mentioned, including a recessional velocity in remarkable agreement with spectroscopic shift, but also for the relative mass of a proton and an electron. I only hope that his theory will stand scrutiny.

OLIVER LODGE

Normanton House,  
Lake, Salisbury

### Leadership and the Royal Society

MANY will sympathise with Dr. Norman Campbell in his desire that the Royal Society should ever exercise that leadership which is its right, all will regret that he should have supported his views by such misleading statements as are contained in his letter in NATURE of March 5. He states that "the only evidence"—of scientific merit—"demanded is a complete list of the candidate's scientific publications." No such list is ever asked for by the Society, no evidence is demanded from the candidate himself.

The Society is bound by its statutes, which provide that "Every Candidate shall be proposed and recommended by a certificate in writing signed by six or more Fellows. The certificate shall specify the name, rank, profession, qualifications, and usual place of residence of the Candidate." The statutes also assign to one of the signatories, acting as proposer, the duty of "informing the Candidate of the Obligation to be subscribed to before he can be admitted as a Fellow", and require that the certificate shall be suspended in the rooms of the Society.

In some cases, no doubt, the proposer thinks it desirable to add to the certificate a list of publications, there is no demand for this, and I agree with Dr. Campbell in thinking that little attention is paid to it. I have taken part in the selection of fellows on many occasions, and do not remember one on which the list was referred to.

Dr. Campbell continues with a list of qualifications about which he says no inquiry is made. Long experience enables me to deny this, and to state that information of the kind indicated is always available and is considered by the council at the time of selection. It is obtained not from the candidate himself—he is asked no questions—but from his supporters and those conversant with his work.

Another statement made by Dr. Campbell is the following: "Election to fellowship confers rights and privileges, it imposes no duties." Let me again quote the statutes: "Every person elected a Fellow of the Society shall, before his admission, subscribe the Obligation in the following words:

"We who have hereunto subscribed, do hereby promise each for himself, that we will endeavour to promote the good of the Royal Society of London, for Improving Natural Knowledge, and to pursue the ends for which the same was founded."

As to those ends, they are to be found in the charter of 1662, here are the words of our founder, Charles II

"... we look with favour upon all forms of learning, but with particular grace we encourage philosophical studies, especially those which by actual experiments attempt to shape out a new philosophy or to perfect the old"

So the King founded the Royal Society, enjoining on the fellows and their successors that their "studies are to be applied to further promoting by the authority of experiments the sciences of natural things and of useful arts"

These are the ends for which the Society was founded, and its long record shows how brilliantly it has set itself, and still continues, to achieve them, working as a band of fellows

It happens that on the morning of Friday, March 4, before I had seen Dr Campbell's letter in NATURE, I wrote a brief note to one of those whose names appeared in that morning's *Times*, congratulating him that I could now claim his help, not as that of a kind friend, but as a brother fellow, and that, I believe, represents the feelings of the fellows towards their colleagues

Of course, fellows do recognise it as their duty and privilege to serve their humbler colleagues. *Noblesse oblige* is their motto, and as a senior member of the Society, I claim that it is still animated by the spirit of its founders, and does care far more for the welfare of science than for the dignity of its fellows

### Complex X-Ray Characteristic Spectra

It is well known that for the excitation of the characteristic X-ray spectra of elements, an electron has first to be removed from some internal level, when this is done, an electron from an outer level jumps to this vacant place, and characteristic radiation is emitted. The spectrum is called *K, L, M* according to the level of the atom from which the electron was first removed

This explanation suffices for the origin of the diagram lines, which show the same structure as lines due to alkalis, but there are, besides, other lines, the origin of which is still a matter of debate. Some of these have been traced to forbidden transitions,<sup>1</sup> but in addition, there are the so-called spark lines, which appear as faint satellites to the diagram lines. Hypotheses<sup>2</sup> have been advanced which ascribe these to double ionisation and single transition

In this note we wish to direct attention to the existence of a third class of characteristic lines, which are due to *double ionisation and double transition*. Suppose in one single act of bombardment of the anticathode by electrons, two electrons are removed simultaneously from an internal level, say one from  $L_1$ , the other from  $L_2$ , and these places are filled up by simultaneous passage of electrons from higher levels, say one from  $M_1$ , the other from  $M_3$ . It can be shown from quantum principles and from analogy with optical spectra that one of the transitions will be allowed, the other forbidden, so that in the above example the transition may be written as  $(L_1 L_2 \leftarrow M_1 M_3)$ , it is a composite transition and is the sum of the two transitions (1)  $L_2 \leftarrow M_3$ , which is allowed, and (2)  $L_1 \leftarrow M_1$ , which is forbidden. Lines due to such transitions are quite common in optical spectra, for example, in the case of Ba  $6s^2 1S_0 - 5d 6p 1P_1$ ,  $\lambda 3501$  cited by Russell and Saunders<sup>3</sup> in their classical paper on the spectra of alkaline earths

There is no reason why double transitions should not occur in the X-ray region. But *their frequency will be approximately double the frequency of the usual L-lines*, and since the electron configuration in this case is  $2s 2p^5 \leftarrow 3s 3d^9$ , the lines will form a multiplet  $(^1P, ^3P) \leftarrow (^1D, ^3D)$ , provided Russell-Saunders coupling continues to hold in such cases. *The fact that their frequency will be double the usual L-spectrum frequency marks them out as a distinct class*

Attempts have been made in this laboratory to obtain such lines from a tungsten anticathode, and two lines have been obtained with the wave-lengths  $\lambda = 723$  and  $682$  X U. They are diffuse lines impressed on a continuous background, and may be found to be attended with satellites when higher resolution is used. These wave-lengths are approximately half the wave-length of tungsten L-lines. After searching the literature to determine whether such lines have been noticed by any previous worker, we find that Rogers<sup>4</sup> noted in 1923 the following lines from tungsten  $\lambda = 1450, 1373, 1321, 1248, 7, 1230, 1114, 1086$  X U. These have not been traced to the tungsten levels, or identified as satellites or non-diagram lines, and cannot be ascribed to any other element. But it will be seen that the wave-lengths of the first two of Rogers' lines are very nearly double the wave-length of the lines obtained by us. Hence it may be safely concluded that the lines obtained by Rogers are the same double transition lines obtained in the second order

The full multiplet will be dispersed over a large wave-length range, and, with our present apparatus, such long exposures (amounting to a hundred hours) are needed that considerable time must elapse before the whole set of lines can be photographed. But the fact that double L-frequency lines have been obtained at all indicates that the ideas presented here are essentially sound

We think that we have established the possibility of getting double transition lines constituting complex spectra in the X-ray region. To get double transition or multiple transition lines due to all elements will be a vast programme, but when this is done, it will probably afford us very useful material for working out coupling problems inside the atom. The idea probably explains the numerous critical levels obtained by Richardson and his students for the most part, these levels have no apparent connexion<sup>5</sup> with the recognised X-ray levels which give rise to the diagram lines. This fact is at present inexplicable, but supposing the quantum theory can be adopted to explain the fact, then combining this with the ideas presented here, we find that we get an unforced explanation of the numerous levels obtained by Richardson, and need not give up the Bohr-Stoner levels (cf Richardson<sup>6</sup>). The *J*-phenomenon also does not appear to be so inconceivable, as according to our views we may have characteristic lines approximately double the frequency of ordinary K-lines \*

### Rotation of Chain Molecules in Solid Paraffins

It is found that the thermal expansion of the crystal lattice of *n*-paraffins is not equal in all directions.<sup>1</sup> The increase in length of the *a* axis measured in the range of liquid air temperature to room temperature is about 7 per cent, of the *b* axis about 2 per cent, whereas the *c* axis remains practically unaltered. This axis is parallel to the chain axes of the molecules.

Recent X-ray measurements on a series of solid paraffins between room temperature and the melting points show that the *a* axes continue to increase at a higher rate than the *b* axes. The result is a change in the lattice dimensions which will be discussed presently. Fig 1 (i) illustrates the packing of the molecules characteristic of all the members of the series. This arrangement is observed when the substances are at room temperature. Fig 1 (ii) is the corresponding pattern near the melting points.

The rectangles represent the boundaries of the cross-section through the unit cell containing the *a* and *b* axes. The long axis of the chain molecule is perpendicular to the plane of the paper. The projections of the chains, which consist of a zigzag arrangement

FIG 1

of  $\text{CH}_2$ -groups, are shown as ellipses in Fig 1 (i). There are two types of orientations present of these ellipses when the crystals are at room temperature. The angle  $\psi$  is between  $67^\circ 10'$  and  $67^\circ 40'$  at  $18^\circ\text{--}20^\circ\text{C}$ .

The angle  $\psi$  depends upon the temperature. It decreases with rising temperature, the expansion of *a* being larger than that of *b*, until it reaches  $60^\circ$  near the melting point. This is found to happen with  $\text{C}_{21}$ ,  $\text{C}_{23}$ ,  $\text{C}_{24}$ ,  $\text{C}_{25}$ ,  $\text{C}_{26}$ ,  $\text{C}_{27}$ ,  $\text{C}_{29}$ ,  $\text{C}_{30}$ ,  $\text{C}_{31}$ ,  $\text{C}_{34}$ ,  $\text{H}_{44}$  and can, therefore, be regarded as the general behaviour of the whole series within that range. If  $\psi = 60^\circ$ , the triangle shown by cross-hatchings is equilateral and the arrangement in (ii) has apparently higher symmetry than the original arrangement (i).

The transition from (i) to (ii) is continuous, that is, there is a gradual change of the two axes *a* and *b* as the temperature increases with  $\text{C}_{21}\text{H}_{44}$  and  $\text{C}_{23}\text{H}_{48}$ . From  $\text{C}_{24}\text{H}_{50}$  onwards all the samples investigated show a sudden transition at about  $5^\circ$  to  $10^\circ\text{C}$  below the melting point of the individual substance. The arrangement after this transition has taken place is still of the same type as (i) and approaches (ii) gradually as the temperature gets near the melting point. These transitions are incidentally those for which Garner and his collaborators have measured the heat of transition.<sup>2</sup>

The change from a less symmetrical arrangement at low temperature to another of higher symmetry at high temperature is not difficult to visualise. The moment of inertia of the chain molecule relative to its axis is comparatively small, and oscillations of large amplitude or complete rotations are to be expected at higher temperatures. Such oscillations obviously tend to produce fields of force round the chain axes which, when averaged, show radial symmetry and produce the simple close packed structure found in the present experiments.

The observations show that too high a symmetry

may be observed in a crystal if the temperature at which the measurements are made is above a certain limit. A similar case for a crystal of amylammonium chloride has recently been discussed by Pauling.<sup>3</sup>

### *Ovis astore*, a Three-Coated Sheep

IN Prof Barker's description of the sheep from Astore (Gilgit),<sup>1</sup> several points which bear upon his subsequent discussion of the development of the fleece of domesticated sheep are not clear. For example, it would be of great interest to know (1) whether the individual animal described is typical of many in that locality, that is, of a local variety or 'breed' or is a crossbred, and (2) the conditions of husbandry under which the animal had been maintained while the coat was grown, since changes of husbandry, including nutrition, can give rise to marked changes in thickness of the fibres throughout their lengths.

The difficulties encountered in endeavours to relate the coat constitutions of domesticated sheep with a two-coated primitive type are mentioned by Prof Barker, but when questions other than those of fibre structure are introduced, the situation becomes more complicated, since a classification of the constituent fibres into two groups is no longer possible. Crew,<sup>2</sup> while insisting upon the two main types of hair and wool, distinguished three groups of *hairs* when classed according to length and colour in the summer coat of *O. ammon poli*. The coat of domesticated sheep exhibits two types of fibre—kemp and wool—and Fraser Roberts has shown that the distinction between these can best be made according to period and duration of growth, the 'heterotypes' of Duerden are fibres which exhibit kemp-like structures for a part of the length. Again, in the normal coat of the Scotch Blackface breed, the so-called 'double-coat' is really a triple coat, since the obvious groups of fibres are (1) kemp, (2) coarse, long fibres, and (3) fine, under-coat fibres.

Fraser Roberts, in a series of papers on "Colour Inheritance in Sheep",<sup>3</sup> discusses the various regional differences in coat pigmentation and describes the types of pigmentation found in individual fibres in the coats of primitive forms, if fibre pigmentation is included, the possible classification of coat fibres is greatly extended. In the Suffolk breed occur kemps, coarse wool fibres, and fine wool fibres, each of which may be, at least, wholly pigmented, non-pigmented, banded, or parti-coloured, and even in the adult fleeces of this breed there appear to be different thresholds of pigment inclusions for the various types of fibre, it having been noted, for example, that the kemps are more likely to be pigmented than are the neighbouring wool fibres growing during the same period.<sup>4</sup> Further, in the Merino breed, with no coat colour pattern, individuals which show 'banded' fleeces are not uncommon, and Boyd<sup>5</sup> recognised four main fibre types which contributed to the gross appearance of these fleeces, with, in one of four Merino fleeces analysed, an additional fifth type.

As Prof Barker suggests, the degree or time of shedding of the fibres in the sheep described may throw some light upon its general coat constitution, but it may be questioned whether there is sufficient evidence

forthcoming from differences in fibre pigmentation to warrant their adoption as criteria in the differentiation of species of *Ovis*.

J E NICHOLS.

Wool Industries Research Association,  
Torridon, Headingley,  
Leeds, Feb 3

<sup>1</sup> NATURE, Jan 23, p 128

<sup>2</sup> *Annals of Applied Biology*, 1921

<sup>3</sup> *Jour of Genetics*, 1924, 1926, 1928, 1930, 1931

<sup>4</sup> *Jour of the Textile Institute*, 1927

<sup>5</sup> *Ibid*, 1930

DR NICHOL'S letter confirms the value of the observations on the sheep which I have, simply for convenience, designated *Ovis astore* in my letter in NATURE of Jan 23. I am still in the midst of my investigations into Kashmir wools for the State Government, but there is already evidence that in a certain district all, or nearly all, the sheep carry double-coats of wool.

About 1912 I was associated with the late Prof T B Wood, of the University of Cambridge, in his experiments in crossing Merino sheep with Shropshire. Messrs Bailey and Engledow came to work with me at Bradford and got out possibly the first diameter frequency distribution curves published with reference to wool. These showed two modes giving the suggestion that two types of fibres—Merino and Shropshire—were being grown in the same (crossbred) fleece. Three years ago I also experimented with the Wembley Merino crossed Lincoln wool. On combing this, the 'top' was very like Lincoln wool and the 'noil' very like Merino wool. Iceland wool is noticeable as yielding a coarser outer-coat fibre and a more valuable under-coat fibre. None of these examples corresponds with *Ovis astore*.

I am surprised that Dr Nichols does not cite such a sheep as the Rough Fell sheep, which, about July, shows an outer-coat growth, and at the roots of the outer-coat fibres an under and shorter wool growth. This under-growth, however, is of fine wool, whereas the *Ovis astore* under-growth is of coarse wool and is sometimes pigmented and sometimes white. Possibly Dr Nichols has had this phenomenon under his eyes and missed it, as I did until coming across *Ovis astore*. The Black-headed Persian is much in evidence in Kashmir and is also being used for crossing in South Africa. Among the woolled skins I have from South Africa is that of a Black-headed Persian x Suffolk Down (twice crossed). This shows a pigmented under-growth of strong fibre. Whether there has ever been the outer-growth of strong hair-like fibres or kemp I cannot say, but it is very probable.

Prof Cossar Ewart and myself were among the first to recognise the kemp birth coat of Merino lambs as possibly the outer-coat of the wild sheep, and it may be that *Ovis astore* will bring into prominence the time of shedding of this outer-coat—early or late. The stronger outer-coat of *Ovis astore* certainly seems to correspond with the black outer-coat of the Black Wolf—the phenomenon of growth is apparently the same in both cases.

Dr. Nichols is scarcely kind either to himself or to me in suggesting that I have mistaken a thickening of the normal wool fibre for a stronger under-growth, and a colour-banding of the normal fibre for a coloured under-growth. This latter phenomenon I became acquainted with some thirty years ago, and I have also read and adjudicated upon Miss Boyd's thesis on this subject.

### Inheritance of Milking Capacity

MR MADSEN's letter in NATURE of Jan. 30 contains much interesting information, based, as it is, upon data unusually numerous and comprehensive. It is with regard to his conclusion concerning the evidence of transmission of some factors for milk-inheritance in a sex-linked manner, based upon the difference in the correlations of the sires to their paternal grand-dams (0.026) and their maternal grand-dams (0.112), that I should like to make two points.

(1) The small correlation to the paternal grand-dam (0.026) might be explained by the choice of the sires by genotypic rather than by phenotypic methods, the merits of the progeny test having been for some time widely recognised in Denmark. The insufficiency of a single cow's record (because it is the expression of a phenotype) in foretelling the production of her progeny, has been stressed by many investigators, and it is doubtful if one should expect to find a significant difference in the correlations of two such records diluted through three generations.

(2) The difference between the correlation coefficients, 0.026 and 0.112, is not significant. From the data tabulated it appears that such a difference would be likely to occur by chance once in ten times. The odds are, therefore, not great enough to warrant the postulation of sex-linkage for some factors, from the data used.

School of Agriculture,  
University of Cambridge, Feb 5

### Contact of Smooth Surfaces

As the result of experiments described in the December number of the *Proceedings of the Royal Society*, Messrs Bastow and Bowden conclude that "When a finely polished plate is lowered on to another polished surface the top plate will sink until the two surfaces are in close contact. The apparent 'floating' at a height of  $4\mu$  is due to dust or particles between the plates." The implication is that the floating is due to particles with a diameter approximating to  $4\mu$ . With the conclusion I agree, since, in spite of many attempts, I have never succeeded in reproducing Sir William Hardy and Miss Nottage's results with carefully cleaned surfaces, with the implication I disagree entirely. In the case of metal plates, the somewhat elaborate apparatus used by Messrs Bastow and Bowden is quite unnecessary. All that is required is to clean the plates with reasonable care, exposed to the air of the room, and lay one on the other as gently as possible. It will then be found that they are in electrical contact.

In my experience<sup>1</sup> it is only with slightly contaminated surfaces that the floating effect is observed, but the point is that the thickness of contaminant is far less than the distance between the plates. When artificial 'dust' in the form of glass fibres is introduced into the gap, the width of the latter increases and is greater than the thickness of the fibres. A film of grease  $1\mu$  in thickness is easily visible on a polished plate, while fibres  $4\mu$  in diameter can be seen without particularly good eyesight. Messrs Bastow and Bowden have made no measurements of the size of the 'dust' which they were 'sometimes' able to see. Surely they do not accuse former workers on this subject of such carelessness that they failed to observe particles  $4\mu$  in diameter, yet if they admit that floating is due to particles of smaller size, the problem remains *in statu quo*.

H E WATSON  
Indian Institute of Science,  
Bangalore, Dec 31

<sup>1</sup> *Proc Roy Soc, A*, 123, 195, 1929

THE experiments described in our paper have shown that small polished plates, *whether clean or contaminated by vapours or liquids*, approach within about 0.3 microns when brought gently together in a dust-free atmosphere. Clean plates showed the same separation *in vacuo*, and this distance corresponded with the known limit of flatness of the plates. Later experiments with polished glass plates up to 10 cm in diameter have confirmed this conclusion, since, when placed together gently in the air of the laboratory, they frequently showed first order interference colours and a mean separation of about 0.3 microns. The exact separation under these conditions depended on the amount of dust present in the atmosphere, but it was seldom as great as 4 microns. There was no evidence for 'floating' either with clean or contaminated surfaces.

In Prof. Watson's experiment, two glass fibres 2.8 microns in diameter were laid on a polished steel plate and a polished steel cylinder placed on top. Instead of sinking down to within a distance of 2.8 microns, the cylinder appeared to float in the air at a height of 15 microns above the plate. After 'prolonged tapping', the air gap decreased to 6.36 microns, but the cylinder would sink no lower.

We have repeated this experiment, using glass surfaces and fibres 1 to 2 microns in diameter. When the fibres were short, there was no 'floating', the separation was equal to the diameter of the fibres. When they were longer than a few millimetres, the separation was frequently as great as 15 microns, but an examination of the fibres showed that they were obviously crinkled. The amount of separation decreased with tapping, and depended simply upon the size of the crinkles.

It is, of course, impossible for us to say whether the same factor was or was not responsible for the large separation recorded by Prof. Watson, but, until there is some convincing evidence for 'floating', we consider that any separation between polished surfaces which exceeds the limits of flatness of the plates by more than a few molecular diameters must be attributed to something much more concrete than a mere cushion of air.

S. H. BASTOW  
F. P. BOWDEN

Laboratory of Physical Chemistry,  
Cambridge

#### Apparent Formation of Copper Carbonyl

AN interesting observation has been made in the laboratory of the Department of Chemistry here on the apparent formation of copper carbonyl in the synthesis of methanol using certain catalysts containing copper.

It was noted that the passage of either hydrogen and carbon dioxide, or water gas, over a catalyst containing equal parts of copper, aluminum, and zinc, produced a liquid condensate which was quite colourless when blown from the high-pressure condenser. However, in a short time, apparently dependent upon the amount of water in the liquid, an evolution of gas occurred which was accompanied by the formation of a yellowish precipitate. Qualitative tests showed that copper was the only metal in this material. The precipitate appeared to be semi-colloidal in nature and was readily soluble in hydrochloric acid, which suggests that the copper was present as a hydrated oxide. This was further demonstrated by the results obtained using hydrogen and carbon dioxide, in which case the liquid contained equal amounts of water and alcohol, and precipitation occurred almost instantaneously upon removal of the pressure. Numerous other catalysts investigated did not show the phenomenon.

The possibility of this precipitate being formed by the hydrolysis of a copper salt formed in the reaction chamber is precluded by the lack of acidity in the condensate. If the evolution of gas were due to the release of pressure, this would occur at once and not after an induction period, as was the case with the water gas condensates. It was further observed that evolution was greatly stimulated by the addition of water, acid, or alkali to the condensates, and even after boiling an alcohol condensate, evolution could be obtained by the addition of water. Such phenomena seem to indicate the presence of a compound with similar properties to those expected of a copper carbonyl.

The analysis of the gases evolved by the liquids was not particularly enlightening, due to the complications added by the solubility of the gases in the liquid. Usually about 1 c.c. of gas was given off by 3 c.c. of liquid, and the composition varied greatly. Carbon dioxide was usually high, averaging about sixty per cent, but fell as low as 10 per cent, carbon monoxide averaged about 17 per cent, but was as high as 80 per cent on one occasion. Hydrogen was invariably low, while hydrocarbons accounted for a fairly constant value of 18 per cent. Interpretation of these results is extremely difficult.

Bertrand<sup>1</sup> claimed the formation of a copper carbonyl at atmospheric pressure, but Mond and Heberlein<sup>2</sup> were unable to verify this result. In our experiments with the above catalyst at atmospheric pressure and various temperatures there was no evidence of the formation of a carbonyl. However, pressure should favour such a reaction, and the product, apparently unstable at atmospheric pressure, would decompose as observed.

The experimental results indicated that the greater the amount of copper precipitated from the condensate, the greater was the activity of the catalyst. If this compound were an intermediate in the formation of methanol, such a result would be expected.

The formation of such an intermediate and the observance of carbon monoxide in the exit gas in the experiments involving carbon dioxide and hydrogen offers a new view on the mechanism of methanol formation which will be discussed elsewhere.

#### Trail of Bright Fireball of Feb. 24

ON Feb. 24, at 20<sup>h</sup> 41<sup>m</sup> GMT, a brilliant fireball passed over West Lancashire from south to north and was observed by many persons who have communicated their observations to me. I did not myself see the object, as I was in the Observatory exposing a plate for experimental purposes on the nebula in Orion, but I noticed the sudden brilliant illumination of the sky and the interior of the Observatory, and made a note of the time. On developing the plate next morning I found that the trail of the meteor was recorded on it, as shown on the accompanying print (Fig. 1).

The path of the meteor is very well defined, making an angle of 35° west of north with the declination circle of the nebula at the time of passage of the meteor. The trace shows well-marked periods of incandescence, and the brilliancy was obviously increasing rapidly during the interval of passage of the object across the portion of its path recorded on the plate, which is of a length of about 8°. This appears

to indicate that the point at which the meteor first became luminous would be not much to the south-east of the nebula.

The accounts received are for the most part descriptive of the appearance of the object which had a brilliant bluish-white head, followed by a tail of considerable length, tapering to a point, and emitting showers of bright sparks. One or two observers note the appearance of brilliant prismatic colours in the part immediately behind the head. Information as to the apparent altitude above the horizon is lacking, but the track on the plate indicates that the meteor would pass a little above the Pleiades. From observers at Blackpool and Fleetwood it appears that the meteor passed a little to the east of the zenith in the former place, and a little to the west at the latter. From this it is deduced that the path of the meteor was approximately N 5° E, passing slightly east of

Fig 1

Blackpool, a line which produced southwards passes approximately over Chester, Hereford, and Bristol—but no information has been received indicating from how far south the meteor was visible.

Owing to the absence of reliable altitude observations, it is not possible to make an accurate determination of the height above the ground, but, taking more or less probable values, it may have been between 15 miles and 25 miles above Blackpool. If sufficient data come to hand to determine an accurate projection of the track on the earth's surface, measurement of the plate will enable an accurate determination of the height and inclination of the path to be made at points near the beginning of the track.

Stonyhurst College Observatory,  
Nr Blackburn, March 9.

#### The Voyage of the *Beagle*

IN the account of the voyage of the *Beagle* in NATURE of Dec 26, 1931, there is a small point that requires correction. This relates to the first appearance of the title-page "Journal of Researches" in Darwin's publication.

His "Journal and Results" appeared as vol 3 of FitzRoy's "Narrative" in 1839, as stated in the article, the publisher being Henry Colburn. The demand for

Darwin's volume was immediately in excess of that of its companions, and Colburn therefore brought out in the same year a separate issue of vol 3. Several preliminary leaves were omitted, and the title under discussion was introduced for the first time. The new title-page reads as follows: "Journal of Researches into the Geology and Natural History of the various countries visited by H M S *Beagle*, under the command of Capt FitzRoy, R N, from 1832 to 1836." Some copies were also issued bearing the date 1840.

In Murray's second edition of 1845, the title-page of the second issue of 1839 was retained with slight alterations. 'Geology' and 'Natural History' were reversed in order, perhaps corresponding with a parallel reversal as to their relative degrees of importance in the author's opinion. The title-page in its altered form runs: "Journal of Researches into the Natural History and Geology of the countries visited during the voyage of H M S *Beagle* round the World".

With regard to Colburn's dealings, the following letter from Darwin to his sister, written in Feb 1842, gives some indication: "Talking of money, I reaped the other day all the profit I shall ever get from my Journal, which consists in paying Mr Colburn £21 10s for the copies which I presented to different people—1337 copies have been sold. This is a comfortable arrangement, is it not?"

Mr Geoffrey Keynes has helped to elucidate the problems of the issues of the first edition, and I am indebted to him for having shown me a copy of a German translation that appeared in 1844, a year before real popularity was attained in England by Murray's second edition. I find that this publication is mentioned in "Life and Letters", vol 1, p 323, where the following quotation is given: "I must, with unpardonable vanity, boast that it was at the instigation of Liebig and Humboldt."

N BARLOW.

Boswells, Wendover

#### Ancient Windmills

WITH reference to the letter under the above heading by Mr H P Vowles in NATURE of Feb 27, p 317, there is in this library a copy of a Chinese work entitled "Ch'i Ch'i t'u Shuo" ("Record of Strange Machines from the West"), which is probably the source of the Chinese illustrations of machines referred to by Mr Vowles. The book, which is on applied mechanics, was compiled in 1627 by Wang Cheng, a Christian convert, and contains fifty-four illustrations of machines, windmills, etc., which appear to have been copied directly from the sixteenth century sketch-books of Besson (1569), Ramelli (1588), and Veranzio (1595).

Our copy of the book was actually printed ("newly engraved") in 1829, but it contains prefaces dated 1627 by Wang Cheng, 1629 by one of Wang's pupils, and 1829. Whether these actually represent three separate editions of this particular work is doubtful, but the same illustrations appear in the great Chinese Encyclopædia of 1726 to which Mr Vowles refers. The interesting point is that Wang Cheng says he compiled the book from information supplied by the Jesuit missionary, John Terrence (1576-1630), who went to China in 1620 and remained there until his death. He was a noted naturalist and mathematician.

The book was exhibited at a meeting of the Newcomen Society in 1925 (*Trans Newcomen Soc*, 6, 85).

## Research Items

**Human Hair and Primate Patterning**—A study of the puzzling problems presented by the human hair has been made by Dr. Gerrit S. Miller and is published by the Smithsonian Institution (*Misc. Coll.*, vol. 85, No. 10). Most solutions offered assume tacitly that all the peculiarities of the human hair arise from man's special constitution and its reactions to the natural environment or to the artificial conditions that man has imposed upon himself, for example, that bareness of skin comes from the habit of wearing clothes, that baldness comes from barbers and wearing hats, that greyness is due to the lessening of bodily energy which goes with increasing civilisation and 'domestication', and so forth. These solutions do not take into account the zoological possibility that many features of the human hair may be generalised primate traits instead of specifically human developments. In other words, they may be special examples of 'patterning', a tendency which attains its greatest development in the primates. Human hair patterning shows itself more conspicuously in the head than on the limbs and body. It is not exactly duplicated in the head of any of the other primates, but all the elements can be found rarely in non-human members of the tribe. In man, both sexes have certain elements in common, but the females' pattern differs in the extension of the bare area over the whole of the base and the sides of the face. The first step in baring the forehead is shown in one of the Celebean macaques, while the essentially human forehead can be seen in the orang. Among non-human primates a bare or nearly bare area round the mouth is usual, while the extension of the bare area to the cheek is seen in the great apes. Yet some, such as the orang and the African guenon, have a beard like a male Caucasian or an Australian. Similarly, baldness, turning grey, and other features, as well as racial differences in man, can be shown to be instances of patterning.

**Contact Modifications in Language**—M. A. Meillet, in a study of the modifications which result when a people changes over from one language to another (*Scientia*, vol. 5, Jan. 1932), points out that the student of the history of languages who confines his attention solely to the language which has survived runs the risk of over-simplification. A language may preserve intact the linguistic type of the tongue from which it derives its morphological characters, as the morphology of the French language contains no elements which are not derived from the Latin, and yet show the effect of influences to which it has been subjected. In the area that is now France two changes of tongue have taken place within historic times. Further, there are elements in French which can be explained as belonging to neither the Gallic nor the Latin tongues, they must be derived from a language spoken before the introduction of the former in the millennium before Christ. One of the effects of the introduction of Latin into Gaul was that a considerable proportion of the population must have become bilingual, and a second period of bilingualism followed after the invasion of the Franks. Of the latter there is evidence in, for example, the inverted form of interrogation after the German model "Kommt er?", the use of *on* = *man*, the use of *rien* from Latin *rem* = *nicht*, the retention of *h*, features none of which was present in Latin. A second modification was the use of one language to express the mode of thought of another, as at the present day in certain localities German thought is expressed in a Slavic language. There is also the

matter of accent, as the Provençal retains the Provençal or Gascon pronunciation of the vowels as opposed to the standard of Paris and the north. Further, tendencies in the earlier language may be inherited and influence the development of the derivative language. Thus certain progressive modifications observed in the Celtic tongue seem to have been carried over and to appear as tendencies influencing the development of French.

**Four-Tusked Elephants**—During recent years there have been several newspaper discussions regarding the possible occurrence of large elephants with four tusks. Field observation tended to show that a few such specimens had been seen. J. G. Dollman has now revised the whole question (*Nat. Hist. Mag.*, Jan. 1932), and shows that various examples are known of abnormally grown tusks, which, springing from a single root, have split into several branches, sometimes quite distinct from one another. Sir Frank Colyer has suggested that sometimes such abnormal growth may have arisen from a divided tooth germ, and that many are doubtless due to injury of some sort—the passage of a bullet or the splitting of the tusk during the prising up of a tree root. It seems likely that such cases may parallel the cases of four-tusked elephants which have been recorded in the field, and that a true duplication of tusks (although mirrored duplication is a common enough form of abnormal growth amongst some animals) has so far not been proved for the tusks of an elephant.

**The Elutriator in Biology**—The *Proceedings of the Lynnean Society of London*, part I, 1931-32, contains a brief account of Mr. A. G. Lowndes's paper on the possibilities of the use of the elutriator in biology. This simple instrument depends on the use of different velocities of water current to effect a grading and separation of the finer particles of a powdered substance, but it is obvious that the method has considerable possibilities in comparing the swimming powers of various fresh water organisms. Mr. Lowndes describes the behaviour of various organisms he has studied. Two species of *Daphnia* with different powers of swimming could be completely separated in the elutriator, and the method would seem to have a wide range of usefulness, both in separating the organisms from mud or silt and in effecting some separation of the organisms from one another. It may also provide a useful method of studying the behaviour of various organisms which attach themselves to a substratum in various stream strengths.

**Research on Tobacco**—In the fifty-fourth Report of the Connecticut Agricultural Experiment Station (*Bulletin* 326) an account is given of experiments dealing with various aspects of the tobacco industry. The practice of topping and suckering the plants is recognised by growers as producing better leaf growth, and the investigations showed that these processes, if properly carried out, would also accelerate the ripening of the leaves, reduce the liability of the plant to wilt and encourage root growth. Tobacco normally produces large numbers of seeds per plant, and the ease with which sufficient seed is obtained has led to a lack of attention being paid to its quality. Trimming the inflorescence, however, so as to allow only a limited number of pods to develop, was found to result in an increase in the weight of seed produced. Leaving some of the upper leaves on the stalk until the pods were mature had a similar effect, and since the

first formed pods in the centre of the inflorescence yielded the heaviest seeds, their selection is recommended. A study was also made of the effect of temperature and humidity on the rate of the process of curing and the quality of the final product. Relative humidities less than 70 per cent or more than 90 per cent were found unsuitable, the best results being obtained with 80-85 per cent humidity at a temperature of 95° F for early and 85°-90° F for late pickings.

**Algæ in the South Indian Cretaceous**—Mr L. Rama Rao, Central College, Bangalore, recently recorded the occurrence of *Lithothamnion* in some of the limestones of the South Indian Cretaceous (NATURE, 128, 225, Aug 8, 1931, 128, 873, Nov 21, 1931). He has since sent a further communication, in which he says he has now recognised algæ in the flints and cherts of the Niniyur (Damian) stage—especially in a band of flints from about a mile south-east of Sendurai. Some of the flints are 'pebbly', nearly 2 cm in diameter, and, under the microscope, are seen to consist of patches of algæ. Others, which are more massive, reveal broad patches of algæ. *Lithothamnion* is common, while several other types of algæ occur. Before silicification, the rock appears to have been largely of the nature of an algal limestone.

**Sedimentation in Coral Reef Regions**—The rate and nature of the sedimentation in coral reef regions is of importance with regard to their formation, and has been the subject of careful studies by Mayor, Vaughan, and others. The latest research is by S. M. Marshall and A. P. Orr, published by the British Museum (Natural History) in vol. 1, No. 5, of the *Great Barrier Reef Reports*. Bottles were placed down on the surface of the reef in different positions and in the anchorage to 3.6 m. Their contents were collected weekly, the contained sediments weighed and graded into size percentages. The loss by solution in 1 in 3 hydrochloric acid in the different grades was calculated, together with the further loss by ignition, and the ash residue. The percentage of the latter is small in the larger grades of sediment, but in the smallest shows varying amounts, 8-29 per cent. It is not clear whence this ash is derived. Almost the only organic material in the same are the frustules of diatoms, the bulk of the ash presumably being carried in suspension from the neighbouring high lands. Three hand borings were driven down to 15 ft through the surface of the reef, and showed mud with little sand below 6 ft. This result was unexpected, the coral reef being a mere capping of a mud shoal. The ash in this mud varied up to 37 per cent, increasing in amount with depth. The last part of the paper contains experiments as to the effect of sediment on living corals. These show that the reef corals when helped by water movements are able to deal with any ordinary amount of mud or sand falling upon them. Coral colonies with large polyps and branching corals are best able to clean themselves, the immense *Fungia* polyps when buried from above almost seeming to "climb through 6 cm of sand unaided." Ordinarily, sediment coming from below, due to movement of sand along the reef surface, "kills in a day or two all the polyps thus covered." We are hence driven to conclude that in protected situations within reefs there is little likelihood of coral colonies being killed by the deposition of sediment. Another explanation thus becomes necessary to explain the barrenness of such areas so far as coral growth is concerned.

**Displacement Pumping of Oil-wells**—The evolution of production methods as applied to lifting oil from the

reservoir after it has ceased to flow naturally has been marked by stages in which ordinary pumping, bailing, and swabbing have gradually given place to gas lift, at least in the penultimate phase of oil-well history. The effect of gas lift is to postpone the time when it is necessary to put the well 'on the beam', as it is termed, that is, the recovery of oil by direct pumping. Actually gas lift is practicable from the first sign of initial decline of oil-flow in the well until either running pressure and rock pressure are equal or until input oil to gas ratio becomes such that the practice has to be discontinued for economic reasons. In the circumstances the search has been for a method which would practically eliminate pumping altogether, for some mechanism which would make it possible to produce oil from the well by appeal to compressed air or gas when other forms of gas lift were impracticable. Displacement pumping, using air, has been known as a hydraulic process for raising varying quantities of fluid over moderate lifts for a long time, the 'displacement pump', of a type now adapted to oilfield work, is a comparative new-comer in this field, the operating medium being either gas or air. It is claimed that this method of bringing oil to the surface is practicable until the well has entirely exhausted itself, to the exclusion of the direct pumping stage altogether. A great deal of experimental work has been done in achieving this notable result in oil-well engineering, and the Institution of Petroleum Technologists was fortunate in learning about displacement pumping from such an able exponent of production technique as Mr Albert Millar, whose paper was read on Feb 9.

**Artificial Disintegration of Aluminium**—The fields close to atomic nuclei can be investigated both by experiments on the scattering of  $\alpha$ -particles and by experiments on artificial disintegration. In the case of aluminium, data obtained in both ways now exist, and are summarised and discussed by J. Chadwick and J. E. R. Constable (*Proc. Roy. Soc.*, Feb). The scattering experiments, due to Riezler, fix the extension of the region within which  $\alpha$ -particles are attracted by the nucleus and the height of the potential barrier at this point at about  $5 \times 10^{-13}$  cm and 8 million electron-volts. Chadwick and Constable's extensive new experiments on the disintegration of aluminium by the  $\alpha$ -particles from polonium show that within this barrier there are at least four energy levels into which  $\alpha$ -particles can be captured. Their value is in the neighbourhood of five million electron-volts, and each is associated with the ejection of two groups of protons. The same picture also accounts for the production of  $\gamma$ -rays when aluminium is bombarded by the  $\alpha$ -particles from polonium, and predicts that their energy should be about 2.3 million electron-volts, which is identical, within the limits of experimental error, with the results of the direct observations of Webster.

**Moving Coil Reproducers and Flexible Disks**—Dr N. W. McLachlan has recently discussed details of moving coil reproducers (*Phil. Mag.*, Jan 1932). He determined the modulus of elasticity of paper and used it to compare the stiffness of conical sheets and disks of the same radius. The combination modes of a reed-driven paper disk are determined, and a comparison with theory shows that the paper must be heterogeneous. The exact solution for a reed-driven disk vibrating in a vacuum without loss is found. The case of a coil-driven circular aluminium disk was examined experimentally, and it was shown that the frequency band occupied by the first symmetrical mode is only five cycles. With constant current in the coil the output at resonance is about

two thousand times greater than at non-resonant frequencies. The author analyses the influence of the magnetic field upon the output and upon the coil impedance of the reproducer. It is shown that the oscillation of a coil driven by an alternating current in a non-uniform magnetic field is accompanied by a motion of translation, and he points out that this is akin to the process of the rectification of an alternating current. A series of impulse records is shown giving the natural damped oscillations of moving coil reproducers of the horn and large diaphragm kind. He deduces that their field of utility lies in the determination of the main symmetrical mode in the upper register and the low-frequency modes associated with the 'surround' constraint.

**Physical Properties of Nitrobenzene**—Mazur has reported (*NATURE*, 126, p 993, 1930) a sharp fall in the dielectric constant of nitrobenzene, an arrest in the heating curve (*ibid.*, 127, p 741, 1931), and a sharp change of slope in the density-temperature curve (*ibid.*, 127, 893, 1931) at a temperature about 4° above the melting point, and the inference to be drawn from these results would be that there are two forms of liquid nitrobenzene. Massy, Warren, and Wolfenden (*J Chem Soc*, Jan) describe experiments on the viscosity and density of nitrobenzene at various temperatures which show no such discontinuities. The density curve is a perfectly straight line and shows

no trace of the discontinuity reported by Mazur. Since the dielectric constant is intimately connected with the degree of orientation and capacity for free rotation of the dipoles of the medium, it is to be expected that the viscosity curve should show a break corresponding with the break in the dielectric constant curve reported by Mazur. Here again no trace of a break was found, the curve being a straight line.

**Kolbe's Reaction**—The mechanism of the formation of hydrocarbons by the electrolysis of salts of organic acids, discovered by Kolbe in 1849, has been the object of a considerable amount of investigation. On electrolysis of potassium acetate solution, for example, ethane and carbon dioxide are formed. Matsuda (*Bull Chem Soc Japan*, Jan) finds that an oxidising substance is formed during the electrolysis, which he identifies as hydrogen peroxide. He considers that acetyl peroxide is the primary product of the reaction at the anode, most of it being decomposed in the earlier stages of the electrolysis as follows:  $(\text{CH}_3\text{COO})_2 = \text{CH}_3\text{CH}_3 + 2\text{CO}_2$ . It may also be hydrolysed into peracetic acid and acetic acid, or into hydrogen peroxide and acetic acid. The hydrogen peroxide will be decomposed in the alkaline solution, so that its amount will begin to decrease at a certain point in the electrolysis. The relation between the formation of hydrogen peroxide and the pH value and concentration of the solution were studied.

### Astronomical Topics

**Geological Studies of the Moon**—The surface of the moon is now known in such detail, thanks to excellent photographs and persevering telescopic study, that it is possible for the geologist to trace the steps of the formation of many of the features. Prof. O. Matousek, of the Charles University, Prague, read a paper a year ago before the Geological Society of America, which is printed in the *Pan-American Geologist*, vol. 54. The Sinus Iridum is the region examined; a diagram shows the various systems of faults, which divide themselves into groups in various directions, the parallelism of each group being very close. Two remarkable dislocations are indicated, in each of which a large region appears to have suffered a lateral shift of several miles. One is in the eastern cape, Heraclides; this is sometimes compared to a woman's head, the portion corresponding to the face has been shifted towards the north-west. The other dislocation occurs in the middle of the coastline of the bay, producing a conspicuous little promontory. Several of the faults are marked by rows of small craters, and the author considers that in these cases at least the craters are genuine volcanoes.

Another diagram shows a vertical section of the bay, the strata being arranged in a manner deduced by the author from a study of the faults, which appear to have caused vertical displacements as well as horizontal ones. The floor of the bay is supposed to be the result of a great lava inundation.

Mr. W. Goodacre read a paper at the February meeting of the British Astronomical Association on a long cleft which he has detected in the south-east region of the Mare Humorum; it does not appear to have been noticed before. It is probably a similar formation to some of those studied by Prof. Matousek.

**Spectra of B-type Stars**—A useful contribution to the study of stellar spectra of type B has been published by Dr. O. Struve (*Astrophys J.*, 74, 225). Thirteen stars, covering all the sub-types from  $O_6$  to  $B_8$ , have been investigated for the purpose of obtaining

a reasonably complete list of wave-lengths and origins of absorption lines in these stars. A list is given of 379 lines between  $\lambda 3820$  and  $\lambda 4924$ , of which 130 are newly identified with known elements. Only 73 still remain unidentified. Wave-lengths are given to 0.01 Å, and origins (in the case of blends) appear in the order of probable importance of the components. Estimated intensities on an arbitrary scale of 1 up to 10 (excluding hydrogen lines, which may be so high as 50) are given for ten typical stars. An investigation is also included of the contours and intensities of the helium lines. Both neutral and ionised helium lines show an expected broadening by the Stark effect, but the relative intensities of He I lines vary in a curious manner. The intensity ratio singlet/triplet is at a maximum at type  $B_2$ , decreasing both towards type  $O$  and (more slowly) towards type  $B_9$ .

**Annuaire Astronomique Camille Flammarion**—This attractive annual (Paris: Ernest Flammarion, 1932, 12 francs) is full of useful information. There are sunspot statistics from the beginning of the century; ephemerides and other information about the planets—it is well to point out that the ephemeris for Pluto, quoted from *Lock Bulletin*, is for the equinox of 1900, this is not stated in the *Annuaire*, the correction for precession is  $1\frac{1}{2}$  minutes of time, which would cause difficulty in identifying such a faint body. An omission in the diagram of future eclipses may also be pointed out, this extends to 1950, but omits the important Norwegian eclipse of July 1945. There are diagrams of the important occultations of the year, which include several of the Pleiades and one of Regulus. There are also tide tables, and comet statistics, which are kept up to date by M. F. Baldet. The stellar information is very full, there are reproductions of stellar spectra, and diagrams of the light-curves of variables. There are star maps for each month, with notes on the phenomena of each month. The book deserves a place on every astronomer's table.

## Ice and the Formation of Alpine Scenery\*

THREE dates stand out as landmarks when a special revival of interest in Alpine glaciology occurred—namely, 1840, when Jean Agassiz published his “*Études sur les Glaciers*”, 1862, when Ramsay read his paper on the glacial origin of lakes to the Geological Society and Tyndall published his paper in the *Philosophical Magazine*, in which he advocated a glacial origin for the Alpine valleys, and 1900, about which time Peach described the Alpine trough-valleys, and W M Davis emphasised the glacial overdeepening of the Ticino Valley, and when, a little later, Penck and Brueckner completed their monumental work on the ice age in the Alps.

It is not until the advent of the eighteenth century that we find any interest being taken in glaciers, then Scheuchzer, between 1706 and 1723, published various works on the natural history of Switzerland which contained some glacial observations, and in which he propounded the dilatation theory of glacier motion. He was followed by Gottlieb Gruner, who in 1760 published his “*Eisgebirge*”, in which he describes the alternate advance and retreat of glaciers, illustrated by an account of the measurements of the Grindelwald Glacier between 1540 and 1750. De Saussure, between 1779 and 1796, published his famous “*Voyages dans les Alpes*”, in which he defined the term ‘glacier’ and classified glaciers under three orders, in this work he also described *roches moutonnées*, which he attributed to water action, and he ascribed the transport of erratic blocks to a deluge or catastrophe. Though usually credited with the view that glaciers moved as solid bodies, his description of the Mount Dolent Glacier as moulding itself to the form of its valley shows that he recognised the plasticity of ice.

In the first half of the nineteenth century a new impetus was given to glacial studies by the observations of Schimper and Esmark and the writings of Venetz, Charpentier, and Agassiz, all of whom attributed the transport of the famous erratics now found on the Jura to the former greater extension of the present glaciers. This view had, however, been anticipated by Hutton.

\* Substance of the presidential address by Prof. E. J. Garwood, F.R.S., before the annual general meeting of the Geological Society of London on Feb. 19.

The publication of Agassiz’s “*Études sur les Glaciers*” did much to stimulate further observation on glacial phenomena during the next few years, but interest again waned after Agassiz’s departure for America.

Ramsay’s paper to the Geological Society in 1862 created renewed interest, fostered by Tyndall’s views on the glacial erosion of Alpine valleys, and discussion was now directed to the work of ice as an erosive agent. Writers on this subject were divided into two camps. Whereas Wallace, Jukes, the brothers Geikie, Logan, Steenstrup, and Penck supported Ramsay, others, including Murchison, Lyell, the Duke of Argyll, Bonney, Rutimeyer, Heim, Credner, and Desor attributed but little erosive action to glaciers.

By the beginning of the present century most observers admitted some erosive action to ice, and more detailed observation focused attention on special features of Alpine scenery. Penck described the trough-shaped characters of Alpine valleys, and Prof. W. M. Davis attributed the hanging valleys and truncated spurs in the Val Ticino to the formation of the trough by glacial overdeepening. The origin of cirques was also discussed and was variously attributed to glacial erosion, water action, and frost action on the cirque wall. The work of Penck and Brueckner had established the occurrence of four glacial and three interglacial periods in the Alps, chiefly on the evidence of the deposits, and the benches which occur on the valley flanks confirm this conclusion. The truncation of the overlapping spurs which occur in the trough valleys shows, however, that the overdeepening must have been largely the result of river erosion during the last interglacial period, the valley having later been widened and modified by glacial action. Certain features, namely, the *arêtes*, cirque floors, the steep south side of the Alps, and in part the hanging valleys, appear to owe their special features to the relatively protective character of ice. The steps in the main and tributary valleys present special difficulties, and cannot be satisfactorily accounted for by simple glacial erosion. They appear to be due in some way to the alternation of glacial and interglacial periods, and may possibly also be due to protection by glaciers during interglacial periods.

## Past and Present Whaling Records

IN the whaling ports which furnished the fleets of the nineteenth century lie many log-books containing records of long years of whale fishing. Charles H. Townsend has struck upon the happy idea of using the old records (in New Bedford Public Library alone there are hundreds of log-books) to obtain information regarding the great whaling grounds, the numbers of whales slain, the position and month of capture, and so on (*Bull. New York Zool. Soc.*, Nov.-Dec. 1931, p. 173).

There are several important collections of whale-ship logs at Nantucket, Salem, and other New England ports celebrated in the history of the whaling industry, but these first records are drawn only from the New Bedford logs and refer only to the sperm whale. Nevertheless, the number of sperm whales represented by the plottings upon the chart accompanying the paper is no less than 11,026. The ‘whaling grounds’, including twelve in the North Atlantic, were visited during fairly definite seasons, as the plottings which

record the position and month of each whale capture show.

In the North Atlantic the plotted areas above latitude 25° show the presence of whales, with few exceptions, during the April-September period, and in the Sargasso Sea the killings are almost wholly confined to the summer period of the northern hemisphere. Between lat. 25° N and the equator, whales were taken chiefly during the October-March season, and along the coast of South America and towards the Cape of Good Hope the catches were largely made during the same season, or summer time in the southern hemisphere. Off Japan and along lat. 30° N the period changes to the April-September season. In the Pacific and to some extent also in the Atlantic Ocean, catches for all months are recorded along the equatorial belts, and the cool Benguela and Humboldt Currents had the effect of creating all-the-year whale fisheries off the west coast of Africa and in the neighbourhood of the Galapagos Archipelago.

It must be remembered that whaling in itself was not a seasonal trade, but that the whalers made voyages lasting from two to four years, catching whales wherever they could, so that the seasonal distribution of the catches of sperm whales is the more significant. The author promises to publish further plottings of sperm whale records and of records of five other species of whales from logs still unexamined, and the results of his investigations will be looked for with much interest.

Records of present-day whaling are giving rise to serious conjecture with regard to the preservation of the number of whales. The number killed during the season 1929-30, according to the *Norwegian Whaling Gazette*, reached the record of 38,563 individuals. Of these, 19,080 were blue whales, 14,350 finners, 1923 humpback, 922 sei, 1352 sperm, and 936 other species. Of the total number, by far the greatest proportion was taken in antarctic waters, 30,654, Japanese waters followed with 1714, and the remainder were captured in

tropical and northern seas. The whaler *Lansving* itself had a catch of 300 whales, shore stations in Alaska and British Columbia had 675. The slaughter of whales has become a much intensified process in recent years. The Norwegian antarctic whaler *Sir James Clark Ross* had seven steam whale-killing boats, a crew of 245 men, and had taken during the season 1445 whales, yielding 55,000 barrels of oil, which were sold to a soap-making firm at an estimated value of one and a half million dollars.

The total world-yield of whale-oil for the season exceeded 3,427,000 barrels, so that, through over-production, much oil had to be stored, and as a consequence there is a slackening off in whaling during the present season. It is a relief to know that the whales will suffer less during a season, but even a years' total respite would help little towards the preservation of slow-breeding creatures like whales, in face of the capacity for slaughter of the new whaling craft.

### Chinese Materia Medica

IN an article in *NATURE* of June 7, 1930, a description was given of the progress that is being made in the elucidation of the botanical origin of Chinese vegetable drugs, and it was pointed out that what might at first sight appear to be a peculiarly abstruse investigation, in which medical historians and anthropologists alone could be concerned, has resulted in a revival of interest in *Ephedra* and the use of its principal alkaloid, ephedrine, in the treatment of asthma.

Prof. Bernard E. Read, to whose labours this practical outcome was mainly due, is continuing these studies, and has published in recent issues of the *Peking Natural History Bulletin* a series of papers on Chinese drugs of animal origin, which have now been issued as a reprint. In preparing these papers, the author has had at his disposal specimens and notes of work done on Chinese materia medica at the Severance Union Medical College, Seoul, and the results of an attempt made by Miss Blanche Wu of the Department of Biology, Yenching University, to arrange the whole fauna used in Chinese medicine according to a modern scientific classification. There is, however, so much unidentified material that such a classification is still impossible.

The subject-matter is arranged in five sections: Domestic Animals, Wild Animals, Rodents, Monkeys and Supernatural Beings, and Man as a Medicine. In each of these sections the particular animals furnishing the drugs are dealt with, and much time and trouble has clearly been expended in relating the Chinese symbols and names to their precise English equivalents. The Chinese doctor was, and probably still is, quite catholic in his taste for drugs, and the article on the pig is reminiscent of the Chicago pork factory, where everything was used but the squeak. This catholicity is not confined to the parts of an animal used, but applies equally to the species regarded as coming within the scope of practical medicine, for man himself figures prominently as a source of drugs. In this respect Chinese medicine is no worse, as Prof. Read points out, than European medicine was in the sixteenth century, and, as he pleasantly puts it, the feverish activity with which every type of animal tissue is being examined for hormones, vitamins, and other specific agents for the treatment of disease "compels an open mind that one may reach beyond the unæsthetic setting of the subject to things worth while." T. A. H.

### Forms of Communal and Industrial Waste

A PAPER read by J. L. Hodgson before the Royal Society of Arts on Jan. 20, discussing "Some Aspects of the Problem of Industrial and Communal Waste", included a number of highly controversial questions, but dealt with many matters which are the subject of much anxious thought to-day and, above all, merit the attention of scientific workers. The contrast between the immense potential productivity of the world, which is largely the result of the application of scientific method and discoveries, and the immense amount of poverty and unemployment which exists side by side with such productive powers, is essentially a challenge to scientific workers whose labours have been a vital factor in increasing the productive capacity of the world. Among other causes of the present position indicated by Mr. Hodgson are not only the numerous forms of industrial waste, but also those forms of communal waste such as armaments, tariffs, unemployment, inadequate housing, sanitary, medical, and educational facilities, restrictions on transport, and, sometimes, forms of rationalisation which tend to reduce the wealth and services available within a community.

These forms of communal waste are the outcome partly of ignorance and partly of vested interests, and they only persist through the absence of impartial scientific inquiry and analysis on a scale competent and authoritative enough to compel rational action.

Among the factors responsible for the present situation, the concentration of credit power in the hands of socially irresponsible people is regarded as fundamental, and in its reaction on industry has encouraged continued increase of technical efficiency, the reduction of wages and staff, replacement of skilled by unskilled labour, mass-unemployment, the formation of mergers or trusts, the growth of tariffs, leading ultimately to restricted output and sabotage of excess products.

Mr. Hodgson, pointing out the absurdity of production which leads only to waste, suggested that strenuous efficiencies are surplus, and that if communal wastes are eliminated and routine work efficiently organised and shared by all, a comparatively small amount of routine will be required of each individual worker. Our aim should be to organise the production of the goods necessary for the maintenance and

development of the community, or their purchase from outside in exchange for commodities produced at home, by the minimum expenditure of effort. In place of the existing credit system, the creation by the Treasury of notes to the value of goods and services available is suggested. These notes would be issued to individuals as wages or endowment, according to age, grade, or services rendered. No one would receive notes which are insufficient in value for the maintenance of a normal, ample life, and while suitable compulsion would be provided regarding a necessary two months' maintenance work, it would be unnecessary to fix an upper limit of remuneration since additional notes would be issued only for actual services and could not be loaned at interest. Under this system no taxation would be required, as the notes necessary to cover all national services would be withheld from distribution. Endowed leisure would be a prominent feature, and the system would definitely lead towards regional specialisation, the exchange between which would be by means of goods.

### Chromosome Studies and Plant Breeding

THE breeding of plants with the object of obtaining new and improved varieties is at best a slow and laborious process, with chances of success by no means assured. Any means of prediction of the probable results of a cross would be of immense value, and Dr Darlington shows in a series of eight papers<sup>1</sup> how far this object may be attained by a previous knowledge of the cytology of the forms to be crossed.

The author passes to the practical view of the question with the minimum of technical detail, and shows how very closely the behaviour of plants in breeding can be correlated with their visible chromosome behaviour. He gives us the picture of a fertile germ cell as carrying a set of chromosomes, which must represent a complete and balanced set of characters, for in exceptional cases such germ cells are able to develop into a new plant without fertilisation. Normally two sets of chromosomes come together at fertilisation and remain associated throughout vegetative growth until germ cells are formed again. In this latter process, an exact pairing of like chromosomes, which afterwards separate, one of each pair passing to each daughter nucleus, is usually associated with the production of fertile germ cells. Irregularity in this pairing frequently results in the production of unbalanced sets of characters in the germ cells, with loss or great reduction in fertility. This is a fundamental point in cross breeding, where the value of the hybrid depends on seed fertility, as in the case of cereals, cherries, and plums.

On the other hand, crosses between plants with different chromosome numbers, which result in sterile hybrids, may have advantages when the plant is required for ornamental purposes and can be propagated vegetatively.

Another interesting fact which has emerged from comparatively recent cytological work is that related species of plants often have either the same chromosome number or some multiple of a basic number; that is, they are naturally occurring 'polyploids'. Work on plants in cultivation and under cytological observation has brought forward facts which are most suggestive as to a possible way in which species may have been derived from one another. This is illustrated by the cross between *Primula floribunda* and *P. verticillata*, which results in a sterile hybrid. Occasional fertile seeds are, however, produced, and they give rise to plants with hybrid

characters, but differing in being fertile and breeding true. Such seedlings—known as *P. Kewensis*—are found to contain twice the anticipated number of chromosomes, and as each parental set has been doubled in such plants, exact pairing is again possible with the passage of two complete balanced sets to each daughter nucleus. The relative numbers of chromosomes in naturally occurring species suggests that hybridisation followed by restoration of fertility by polyploidy is one possible method of their origin.

These and many other problems are dealt with fully in these papers. Although, as Dr Darlington points out, the knowledge gained by a preliminary chromosome investigation cannot control the results obtained by a cross, it may be of great value in directing the activities of the plant breeder into lines which have some hope of success.

### University and Educational Intelligence

CAMBRIDGE—An appointment to a University lectureship in mathematics will be made in the Easter term, to take effect from Oct 1. The initial basic stipend is £200 a year, but an additional allowance of £150 a year may be granted to a lecturer who is not a fellow of a College, and also a number of years' seniority carrying with it an increased basic stipend. Candidates are requested to send their names, with any evidence of qualifications which they may desire to submit, to Mr W J Harrison, Secretary of the Faculty Board of Mathematics, Clare College, Cambridge, on or before April 30.

The examiners consider that the following submitted essays of distinction for the Smith's prizes and Rayleigh prizes: D W Babbage (Magdalene College), "Cremona Transformations"; J Bronowski (Jesus College), "On a Representation of Primals"; J Cossar (Magdalene College), "On Fourier Integrals"; V V Narliker (Non-Collegiate), "Cosmogony and Astronomical Dynamics"; H M Taylor (Clare College), "The Anomalous Scattering of X-Rays". The Smith's prizes are awarded to D W Babbage and H M Taylor, and Rayleigh prizes to J Cossar and V V Narliker.

Dr J A Venn, Gilbey lecturer in agriculture in the University, has been elected president of Queens' College.

LONDON—The degree of D Sc in chemistry has been conferred on Frank Bell (Battersea Polytechnic) for a thesis entitled "Polarisation and Chemical Reactivity in Aromatic Substances" (*J Chem Soc*, 1928-30).

APPLICATIONS are invited for the Henry George Plummer fellowship in pathology of the Imperial College of Science and Technology, for research in morbid anatomy, histological anatomy, chemical pathology, protozoology, bacteriology, or allied subjects in either zoology, medicine, or botany. Applications must be made by letter to the Rector, Imperial College of Science and Technology, Prince Consort Road, S W 7, by at latest June 11.

An election of Beit junior memorial fellows for medical research will take place in July next and applications for them are invited. The annual value of each fellowship is £400 and the tenure usually three years. Forms of application and full information may be obtained by letter addressed to Prof T R Elliott, Honorary Secretary, Beit Memorial Fellowships for Medical Research, University College Hospital Medical School, University Street, W C 1. Completed forms of application should be returned by May 18.

### Calendar of Geographical Exploration

March 21, 1699—Abyssinia via the Nile

A Jesuit, Father de Brèvedent, and a French doctor, Charles Poncet, reached Sennar. They left Cairo in June 1698, went down the Nile to Siout, and then struck across the desert and passed through Dongola to Sennar, reaching the Blue Nile above its confluence with the White Nile. Leaving Sennar, they recrossed the Blue Nile, reached the Gundwa, the headstream of the Atbara, and arrived at the borders of Abyssinia, where de Brèvedent died. Poncet entered Abyssinia, and stayed there until early in 1700, when he returned to Massaua. Poncet's journal gave much information about the regions through which he passed, and especially about their natural history.

March 21, 1871—Henry Morton Stanley

Stanley's remarkable series of African explorations began on this date with his journey from the east coast of Africa to Ujiji, where he met Livingstone and with him explored the northern shores of Tanganyika. His next expedition, 1874-77, from east to west of Central Africa, resulted in the mapping of the course of the Congo River, in a knowledge of the relation of the Kagera to the Nile, in the discovery of Lake Dwera, and in the solution of many other geographical problems of the region. In 1887-90 he discovered the Ruwenzori Mountains, traced the course of the Semliki River, discovered Lake Edward Nyanza and the great south-western gulf of Victoria Nyanza. Much information about the pygmy tribes of the Congo forest was collected. His journeys outlined the main facts of the sources of the Nile, and completed the work of the earlier explorers of the Nile and of Livingstone and Cameron.

March 22, 1830—Mouth of the Niger

Richard and John Lander arrived at Badagry, on the Slave Coast of the Gulf of Guinea. They then made their way inland to Bussa, on the Niger River, the journey occupying three months. After careful preparations, they embarked on the river in two canoes and sailed down it to the Atlantic Ocean, thus at last clearing up the course taken by the Niger River. They also found that the Benue River joined the Niger. Their courage in entrusting themselves in such frail barks on an unknown river and in facing the dangers of tropical diseases, hostile tribes, and uncharted rocks, dangers which had already taken toll of many previous explorers, was rewarded by the solution of a problem upon which Mungo Park and Clapperton had worked. It is interesting to note that a 'stay-at-home' geographer, James M'Queen, had fourteen years previously correctly mapped out the course of the Niger on scientific principles, and had proved that it could only terminate in the Bight of Benin.

March 23, 1843—Middendorf in Siberia

A. T. Middendorf left Turukhansk, went down the frozen Yenisei, and thence over the tundra to the basin of the Khatanga River. He then proceeded northwards to the Taimyr peninsula, and, in spite of many hardships, brought back valuable descriptions of the life of the region. Later he journeyed from Yakutsk to the Sea of Okhotsk, crossing the Stanovoi Mountains and exploring the Amur basin as far as Lake Baikal. Middendorf's accounts of the regions he traversed are of great scientific value, especially for the study of the flora and fauna of Siberia.

March 24, 1921—R. E. Cheesman in Arabia

Major R. E. Cheesman started his exploration of the coast-line of eastern Arabia, near the island of Bahrein, at the Bay of Salwa. The coast between Oqair and Salwa had never been visited by a European, though Burchardt in 1904 passed Salwa on a different route. Cheesman made a route traverse of the coast, accompanied by a sailing boat which carried his chronometer. He was much interested in the ruins of Salwa, which may have been the Phœnician Gerra. In 1923-24 Cheesman explored the desert of Arabia southward from Hofuf, discovering the oasis of Jabrin, previously unvisited. A feature of his work was his record of bird life in the regions which he visited.

### Societies and Academies

#### LONDON

Institute of Metals, March 9—J. Newton Friend. The relative corrodibilities of ferrous and non-ferrous metals and alloys. (3) Final report. The results of three years' exposure at Southampton Docks. The metals examined included lead, zinc, tin, aluminium, copper, nickel, and various alloys containing iron, chromium, nickel, copper, and zinc. Nickel-copper alloys, particularly the 70/28 alloy, offered great resistance to corrosion. High-grade zinc and tin were slightly more attacked than the less pure metals. Tension, riveting, and cold-working did not appreciably affect the corrosion of nickel-chromium alloy steels, but in every case cracks appeared at welds. Alloy steels resisted corrosion well, they are subject to serious localised corrosion.—O. F. Hudson and J. McKeown. The properties of copper in relation to low stresses. The effect of cold-work, heat-treatment, and composition. (1) Tensile and compression tests under short-time loading. The tensile tests have shown that all the materials tested possess a certain limit of proportionality due to the applied cold-work, and that this limit of proportionality can be considerably raised by suitable heat-treatment. There is a superior resistance to deformation brought about by cold-work and suitable heat-treatment, and also a greater resistance to deformation conferred on copper, particularly at elevated temperatures, by the presence of a very small percentage of silver and also by the presence of tin and silicon.—H. J. Tapsell and A. E. Johnson. The properties of copper in relation to low stresses. The effect of cold-work, heat-treatment, and composition. (2) Creep tests at 300° C and 350° C of arsenical copper and silver-arsenical copper. Improvement in resistance to creep at 300° C and 350° C is effected by the special pre-treatment of the alloys, and alloys containing 0.072 per cent silver are superior to the silver-free alloys.—R. Seligman and P. Williams. The interaction of aluminium and water vapour. The statement having been made recently that aluminium and its alloys are rapidly attacked by super-heated steam at 300° C, the authors have made experiments and have found that no such attack takes place under the conditions which they define.—F. Bollenrath. On the influence of temperature on the elastic behaviour of various wrought light metal alloys. The elastic properties increase with decreasing temperature, except in the cases of two aluminium alloys with a high silicon content.—D. Hanson and C. E. Rogers. The thermal conductivity of some non-ferrous alloys. Aluminium-copper alloys were tested, also the effect of aluminium, nickel, iron, phosphorus, and arsenic on the thermal conductivity of copper.—A. J. Sidery, K. G. Lewis, and H. Sutton. Intercrystalline corrosion.

of duralumin. Partial immersion in a *N*-1 solution of sodium chloride to which 1 per cent (by weight) of hydrogen chloride had been added was capable of producing intercrystalline corrosion consistently in samples of duralumin where a propensity towards this type of corrosion existed. Overstrain in tension increased slightly the tendency towards intercrystalline penetration, but no relation was observed between this tendency and the degree of elongation. In general, the higher the quenching temperature the smaller was the tendency of the material to develop intercrystalline corrosion.

## PARIS

Academy of Sciences, Feb. 1 — A. Cotton, G. Dupouy, and M. Scherer. The magnetic rotatory power of blende and the measurement of the fields of electromagnets furnished with perforated pole pieces. Utilisation of magnetic rotations of thin plates of blende for the measurement of intense magnetic fields — Gabriel Bertrand. Can gold be considered as one of the elements of living matter? Berg has stated that gold is present in the brain of the ox in the relatively high proportion of 14 mgm. per kilogram of dry substance. The author has repeated Berg's experiments with negative results. If the ignition is conducted in a platinum vessel a trace of this metal, but no gold, is found after following Berg's process, but after ignition in silica there is no trace of either platinum or gold — E. Mathias. Variation of the surface tension of fulminating material as a function of the temperature and molecular weight — Ch. Porcher and A. Tapernoux. Search for indoxyl (indican) in cow's milk and goat's milk. A criticism of a recent communication by Ch. Hervieux. The thymol reaction for indoxyl derivatives is not trustworthy — Paul Boum was elected *Correspondant* for the Section of Anatomy and Zoology — Th. Anghelutză. A functional equation — Gaston Julia. The reconstruction of a  $\sigma$  Riemann surface corresponding to a multiply connexe area  $\Omega$  — Jean Pierre Robert. Riquier's problem and its generalisations — M. Ghermanesco. Certain systems of linear partial differential equations of the elliptic type — F. Leja. The domain of convergence of series of homogenous polynomials — Edouard Callandreau. The maximum strain in a plane body perforated by a circular hole — Sonier. Thin rectangular plates submitted to variable forces — Michel Luntz. The virtual profiles of least resistance — D. Barbier. The probable periods of visual double stars the orbit of which is still unknown — Bernard Lyot. The study of the solar corona with the spectroheliograph otherwise than during an eclipse. In a previous communication the author has given an account of how he saw and photographed the green and red lines of the solar corona with a direct vision spectroscope. These experiments have been repeated with two spectrographs of much greater dispersion and with a spectroheliograph. The results described prove that by these methods it is possible to study the green and red lines of the coronal spectrum at any time, and in a more complete and exact manner than during eclipses — N. Gunther. The Newtonian potential — A. Schweitzer. The variation of dimensions produced by annealing cold hardened copper — J. Jaffray. Some properties of vacuum thermocouples. Supplementing an earlier communication, the effect of the variation of the external temperature has been studied and a method of correction worked out — André Chevallier and Pierre Dubouloz. Intensity measurements in the ultra-violet spectrum by means of photoelectric cells sensitised by sodium salicylate. In an earlier communication the authors have described the application of a potassium photo-

electric cell, sensitised by sodium salicylate, to the study of the ultra-violet. It is now shown that the curves obtained giving the intensity of the fluorescent light as a function of the wave-length agree closely with those obtained by other methods — Mlle Suzanne Veil. The action of the electric field on gelatine. The effect of the presence of an indicator. Deformations undergone by gelatine in an electric field correspond with physico-chemical changes in the medium — P. Jacquet. Study of the tensions in electrolytic copper deposited in the presence of gelatine — René Pallu. Study of the system  $H_3PO_4$ ,  $Ca(OH)_2$ ,  $CO_2$ ,  $H_2O$  — T. Karantassis. The action of hydrocyanic acid on the halides of the tervalent and tetravalent metals. The existence of the compounds  $TiCl_4 \cdot 2HCN$  and  $AlCl_3 \cdot 2HCN$  is proved — A. Maille and Renaudie. The transformation of ketones into liquid hydrocarbons. Using silica gel as catalyst, ketones (acetone, propione) gave a mixture of aromatic and unsaturated hydrocarbons with a small proportion of naphthalene and anthracene — A. Wahl and R. Lantz. The preparation of some new derivatives of  $\beta$ -naphthol — F. Salmon-Legagneur.  $\beta$ -Homocamphoric acid. A new mode of formation of  $\beta$ -camphor — Émile André and Charles Vernier. The *d*-cinoleates of  $\alpha$ -phenylethylamine and *l*-ephedrin — Dalloni. The Silurian grits and intrusive alkaline rocks of the older formations of Tibesti — André Demay. The fragments of Hercynian overlapping near Vivarais — Chadeaud. The chondriosome of the green algae — Mlle Lucienne George. Observations on *Sorbus torminalis* — Aug. Chevalier. The places deprived of vegetation in the Sahara and their cause from the point of view of plant ecology — Friant. The influence of the size of the body on the dental morphology of mammals — Jules Amar. The hydrothermal coefficient in homeotherms — René Hazard. The action of sparteine on the inversion by yohimbine of the vasoconstrictor effects of adrenaline — A. Auguet and J. Lefèvre. Curves of loss and of metabolism as a function of the external temperature in the homeotherm in repose — A. Policard and A. Morel. The utilisation of the spectrography of lines in histochemistry (histospectrography). A modification of the method proposed by W. and W. Gerlach for which some advantages are claimed — R. Pussard. A parasitic nematode of *Psylla* — Ph. Lasseur, A. Dupaux, and M. Grojean. Factors of stability of bacterial suspensions heated to 80° C. The remarkable stability of bacterial suspensions after heating to 80° C., is explained, at least in part, by a decrease in the surface tension of the dispersed medium, an increase of the electric charge, and an increase in the viscosity — Pilon and Codvelle. The action of metallic copper on the germs in drinking water.

## LENINGRAD

Academy of Sciences — *Comptes rendus*, No. 10, 1931. — A. P. Vinogradov. Colorimetric determination of vanadium by the method of phospho-tungstic acid. The method, which is described in detail, is particularly suitable for the determination of vanadium in living organisms — V. P. Rusakov. Radioactivity of phosphorites and their extracts. The average radioactivity of phosphorites exceeds considerably that of more common soils and rocks. The radioactivity of water extracts from phosphorites is very weak, of the order  $10^{-12}$  per cent of radium. The radioactivity of extracts made by 10 per cent solution of hydrochloric acid is, on the average, of the order  $10^{-10}$  per cent of radium — V. Milchevskaja-Rutkovskaja. Rubidium (and caesium) in microclines from different localities — E. Krinov. The meteorite of Staroje Borisino. Description of a meteorite which fell on April 20, 1930,

65 km north of Buguruslan —C Flerov Data on the craniology of the family Equidae Craniological characters of the recent members of the family are tabulated and discussed The conclusion is reached that they all form one genus, *Equus*, with three subgenera, namely, *Equus*, including the domestic horse and *E. przewalski*, *Asinus*, comprising Asiatic and African wild and domestic asses, and *Hippotigris*, which includes zebras and quaggas —B Galerkin The flexion of thick elastic plates, rectangular and triangular, poised on their contours A contribution to a solution of the problem of theory of elasticity in the case of three dimensions, with the aid of functions of tension and displacement

## Forthcoming Events

### FRIDAY, MARCH 18

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS (Annual Meeting) (at the Middlesex Guildhall, Westminster), at 3 —Chairman Earl Buxton Speakers Viscount Grey of Fallodon and J H Whitehouse

GLASGOW CHEMICAL SOCIETY (Annual General Meeting) (at Glasgow University), at 4 —Prof G G Henderson Publication of Chemical Literature (Presidential Address)

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5 —Annual General Meeting, followed by an Ordinary Meeting —A S Rao The First Spark Spectrum of Arsenic (As II) —J S Rogers The Photographic Measurement of the Absorption Coefficients of Gamma-rays from Radium (B+C) —M Fahmy On the Derivation of Maxwell's Equations from the Equations of the Quantum Theory

UNIVERSITY COLLEGE, at 5 30 —Prof A J Toynbee The Turks (Lecture)

IRON AND STEEL INSTITUTE (Annual General Meeting) (at Royal Technical College, Glasgow), at 7 15 —W E J Lewis Notes on Autogenous Welding

## Biology in the Schools

APART altogether from the importance of biology as a vocational study—biology for bread—upon which the Chelmsford Report laid emphasis (*NATURE*, Feb 20, p 257), there is the wider and more humane aspect of biology as an appreciation of the unity of living things, and therefore as the link between the individual and all his environment—biology for life

Why is it that the value of this appreciation, as something that adds interest to life and has a social value as well as an intellectual, has not been sufficient to compel the inclusion of biology in the work of the schoolroom? Of its definite exclusion from the school there can be no doubt, in spite of the exceptions which emphasise the rule. Nothing could be more encouraging to the enthusiastic biologist than, say, last year's annual reports of the work done by the natural history societies at Eton, Marlborough, and a few other schools, they show a grasp of the possibilities of Nature study, an appreciation of the zest of discovering new things, and, above all, an intense keenness in this branch of study which combines learning with investigation. But these are shining lights, the vast majority of the children of Great Britain walk in biological darkness to them the opportunity of this ever-fresh interest is denied. Of eighty-six medical students going to one of our northern universities this winter for the first time, six had learned a little botany, the others had neither botany, zoology, nor biology—a measure of the lack of biological teaching in the schools of the north, and probably the condition is repeated, though, we trust, not so decisively, in other regions of the kingdom.

One of the deciding factors in the area we refer to is the exclusion of biology and related sciences from the subjects for proficiency in which competition bursaries are awarded. The bursary competition enforces a trend of curriculum in the schools as inevitably as the scholarship examinations and awards at Oxford and Cambridge have been found by the Chelmsford Committee to enforce over-specialisation within a limited range of subjects.

A second deciding factor against biology as a school subject has been the well-entrenched position of physics and chemistry in the curriculum as representative of the observational sciences. With this may be associated the fact that it is probably easier to devise a suitable observational and experimental course with inanimate material than

with living organisms, and consequently that the proper teaching of biology is more difficult and the supply of adequately trained teachers much more restricted

These factors lie outside the direct influence of the biologist, but the third factor which has hindered the adoption of biology in the schools lies with the biologists themselves—they have failed to give a decided lead as to what biology in the schools is to connote. It is regarded as a vague term, covering a multitude of ill-defined interests, or it is looked upon as simply a little botany plus a little zoology, each almost or altogether isolated in its own compartment. Within the last year or two, many books devised for the teaching of biology in schools have been published, and their variety in range, in subject matter, and in treatment shows how earnest an endeavour is being made to meet the demand for guidance, but at the same time it exposes the difficulty with which the willing but less experienced teacher is faced when he has to choose between so many possibilities.

We would be the last to suggest that a formal and set course in biology should be imposed upon such schools as desire the subject, for it is one of the attractive features of biology that it can and should adapt itself to the special environment of each locality. But we do say that now is the time for indicating the content of biology as best fitted for the interests of pupils in schools, and of giving a skeleton form to a subject which to many appears to be so vague as to be almost formless. Otherwise, how can it be expected that school managers or governors, unacquainted with the subject at first hand, will be able honestly to decide that here is a branch of science eminently suited and highly desirable for inclusion in the curricula of the schools under their care?

In the devising of such a course, which is to influence and appeal to a vast majority of pupils who will never enter a university or apply biology professionally, the constant aim must be biology for its interest, its outlook, and its understanding—'biology for life'.

The problem of the biology course is not confined to Great Britain. For twenty years and more the subject has been taught in the high schools of the United States of America, and so long ago as 1905 the State of New York issued its first syllabus in biology. The result was definite and encouraging, for work in the new field developed rapidly and met with unusual success. It was accompanied by an increasing desire to keep the science

teaching in the schools in touch with the experience of the pupil in his own environment, and there followed the State's syllabus in general science in 1925. On this a broad foundation of scientific knowledge has been laid, and it is testimony to skilful planning that in its turn the growing emphasis upon the work in general science has demanded a further step in evolution, and that is the development of a broad course in general biology to cap the training in general science.

This new course, the substance of which has just been published,\* is the result of a year and a half of consideration by a committee of science teachers and educationists selected for the purpose. It aims at rounding off the science training of the schools by bringing within the range of the many adolescents in the secondary schools the larger conceptions of biology, therefore it presupposes the existence of an earlier training of one to three years in general science. It is worth while considering the nature of this foundational training, for upon its soundness the fate of the edifice must rest.

There is universal agreement, the committee states, that the preparatory general science should deal with the environment, and should centre about the pupil as the interested focus of his or her environment. "General science should not consist of a succession of physical, chemical, biological, astronomical, and similar topics presented chiefly as a survey of these different sciences. The purpose of general science is not to acquaint the pupil with the various sciences as entities in themselves," but to lead him "to investigate as an individual the various phases of the environment as they impose themselves upon him."

That seems to be a simple limitation, but it is far from being so simple as it looks, and accordingly it has been found that the teacher, perhaps following his own bent rather than the child's, perhaps because it is easier, has often strayed much further into, say, the "practical and mechanical application of physical principles and into the abstract underlying laws than is justified by the attitude of enquiry on the part of the pupil." Nevertheless, the rule is that general science in its early stages should deal with immediate environment, and that every lesson should start off from the outlook of the pupil, with all its limitations and immaturities—that is sound teaching, which should lead the pupil gently into varied fields of chemistry, physics, and simple biology.

\* Tentative Syllabus in General Biology, published by the University of the State of New York, Albany, 1931. Pp. 62.

On ground thus prepared, the course of general biology is to be laid. It opens and it closes with man in the centre of the picture, played upon by, and in turn playing upon, his environment. The reason for the prominence given to human relations is that studies organised with their focus upon humanity will prove to be psychologically most interesting to the pupils. We do not feel convinced that the insistence at this stage upon the dominance of human contacts is essential, since the interest of the majority of pupils at the age contemplated is easily held by the study of any living thing. But few will cavil at the guiding principles of interest and largest social value which have determined the actual selection and arrangement of the content of the course, or at the endeavour of the committee to arrange the material in a sequence of "dependent continuity and ascending difficulty."

The programme for the course of general biology falls into four sections, divided into two parts—apparently for the convenience of the teaching year, for there is no real discontinuity between the two. The first section deals with "man's place in the world of living things", and the breadth of the treatment is indicated, but only roughly, by the three themes (each to occupy about three weeks of school time) round about which the lessons are grouped—"Man is one species among millions of diverse species", "There is unity among all living things", "Living things and their environment are constantly changing". From simple observation, comparison, and identification of types of plants and animals, and the recognition of diversity of form, the pupil is led to inquire into the significance of similarities and differences, and having associated changes in environment with changes in organisms, he is drawn by inductive methods to the acceptance of evolution as the simplest explanation of these phenomena.

"Self-preservation among living things" is the general subject of the second section, with three supporting themes—"All living things have the same problems", "Living things bear different nutritional relations to their environment", and "Living things have to relate themselves to their environment". The section begins with a study of the activities of single-celled organisms, and of the specialisation which these activities and their associated structures undergo in multi-cellular organisms, nutritional activities are selected for special discussion, and this leads to consideration of the contacts with environment made by the organism through sensation and response.

The topic of self-preservation is followed, in section three, by that of "Race-preservation among living things", and this gives opportunity for a comparative study of reproductive methods, leading to consideration of the cell-basis of reproduction and so to the cell in heredity, to the outlines of plant and animal breeding, and of inheritance in mankind.

In the final section, entitled "Man's increasing control over his environment and over himself", a wide range of possibilities lies before the teacher, for there must be considered typical ways in which environment is 'improved', say, by cultivation and by warfare against other organisms which are inimical to human welfare, and so to the balance of Nature and its unstable equilibrium. Last of all is traced the progress of man as a biological phenomenon, with a unique and accumulating social heritage, and a slow development from the eolith-maker to the time when the domestication of animals hastened the pace towards the scientific age, at the beginning of which we stand to-day.

In the consideration of this ambitious scheme of biological teaching for the secondary school, several important facts must be borne in mind. In the first place, the syllabus, which in the above summary must appear to be despairingly vague to the teacher who longs for a prescribed course of details, has been deliberately denuded of factual content, so that the teacher himself, keeping in view the emphasis upon great biological truths, may adapt the lessons to the particular needs of the urban or rural district in which he is placed. Many hints as to possible modes of treatment are given in the 62 pages of the "Syllabus". In the second place, the syllabus does not stand by itself, but is correlated with an earlier body of general scientific knowledge, and the general biology course is to be succeeded by detailed work in the sciences of chemistry and physics. In the third place, the syllabus is regarded as suggestive rather than final, and it is accompanied by a request to teachers for constructive criticism.

Even before the syllabus meets the test of actual trial, however, it will be recognised that the Committee has done a useful work in emphasising the close relationship between biology and the social sciences, and in making a determined step towards the creation of a co-ordinated programme of science tuition which will endow pupils about to leave the upper schools with the broadest values likely to be obtained by the application of the scientific method.

### Can Nature be Explained?

*Mind and Matter.* The first of two volumes based on the Gifford Lectures delivered in the University of Edinburgh in 1919 and 1921. By Prof G F Stout. Pp xiv + 326 (Cambridge At the University Press, 1931) 12s 6d net

PROF STOUT writes in a rather antiquated philosophical dialect which makes it difficult in many places for a reviewer by about half a century his junior to be sure exactly what he means, and still more difficult to separate his main argument from incidentals. So far as I understand it, Prof Stout's book is an attempt to provide a theory of the relation between perceiving minds and physical objects which shall not violate common sense, as he considers, and I think rightly, that it is violated by two of the most notable types of theory, both by what Prof Moore has called the *Mill-Russell Type*, which minimises or eliminates unperceived physical events, and by the Cartesian type of theory, according to which percepts are only representations or reflections of physical events.

The Mill-Russell type of theory regards physical objects as sets of actual and possible sense-data, to say that a possible sense-datum exists simply means that had there been an observer at a certain place and time, where and when in fact there was none, he would have observed a certain kind of sense-datum. But according to common sense this sort of hypothetical proposition is true, and can only be true because there is a physical object which the supposed observer would have perceived, and which existed although at the time in question no one perceived it. According to the Cartesian type of theory, sense-data are events which represent and are caused by physical objects, but are not parts or aspects of them, and it is with sense-data alone, and not with physical objects, that we are acquainted, as this phrase was used by Lord Russell in "The Problems of Philosophy". But the view of common sense is undoubtedly that when we perceive physical objects we are in some sort of sense in contact with them, and not merely in contact with some medium between them and ourselves.

Prof Stout begins the construction of a more congenial theory by an account of what he calls *the animism of common sense*. It appears to him, as it has to other philosophers, that our understanding of physical processes is increased by the organic sensations which inform us about our own bodies. There are at least two distinct ways in which this suggestion can be applied. If, for example, I support a heavy object in my hand, I

have an experience which may be called a feeling of weight or pressure, it may then be said that the object of my feeling is characterised by a certain quality which I shall call strain. Now, if I watch a parcel being weighed on a spring balance, as the spring is compressed it is possible that it is characterised by a quality similar to this quality of strain—of course without the accompaniment of anything comparable to my experiencing of the strain. I do not see conclusive reasons for rejecting this form of animistic explanation. But on the other hand it may be thought, as Leibniz appears to have thought, that while we understand how our own actions take place, because our knowledge of them comes as it were from the inside, we cannot understand how any action takes place which is not that of a living organism. Thus we can only understand what happens when the parcel rests on the balance if we suppose that as the parcel descends the spring spontaneously contracts to make way for it, like a dog shrinking before a blow.

Now, so far as I can see, though Prof Stout does not actually assert that this sort of view of Nature is true, he does ascribe it to common sense, as the champion of which he appears. But I think it is clear that common sense, on the contrary, makes a very definite distinction between mechanical and vital occurrences, and would consider that when, for example, the dog shrinks from his master's raised hand, he is in some sense behaving vitally in order that he shall not be subject to a certain kind of mechanical occurrence. I think it is clear also, quite apart from the question whether we do in any proper sense understand our own actions better than we understand mechanical events, that the alleged fact that we can only understand these mechanical events by interpreting them animistically is no ground for thinking the animistic interpretation true.

After a long consideration of previous psychophysical theories, Prof Stout goes on to state his own view of perception. His fundamental contention is that "physical existence which is immediately known is never actually experienced as sensations and feelings are", "we know immediately and not by inference the actual existence of what is not actually experienced", and he develops this by saying that "when I try to fix attention on a sensum or feeling as such. I can only distinguish it within a context [which] always includes real existences which are not being actually experienced". From the passage which I have quoted last, it appears as though the things which Prof. Stout refers to as immediately known though not

experienced are such things as peripheral sight-data which are not being attended to. But whether or not he refers to events of that sort, he certainly does refer to physical objects. He asserts then that physical objects are not actually experienced, I think it is quite clear that this means that physical objects are not sense-data or constructions from sense-data, and he asserts that they are nevertheless in some sense or other immediately known. Obviously this cannot mean that we know them by acquaintance, as that phrase is defined in "The Problems of Philosophy", for if we did it would follow that we experience them. Prof Stout elucidates his use of the phrase *immediately known* by analogy with memory. In his meaning of the phrase, when I remember my last visit to the dentist I immediately know that visit, although I am not experiencing it. Now it is clear that when this memory is before my mind I know and am aware of the fact that I did visit the dentist at a certain time, and this may be what Prof Stout would understand by the statement that I immediately know the visit. If so, to say that I immediately know a physical object presumably means that I know and am aware of the fact that a certain physical object is in a certain place. It may well be true that I sometimes know and am aware of facts like this, even if physical objects are not composed of or constructed from sense-data. But is it a novel truth?

Prof Stout's final account of the relations between physical objects and sense-data is that "the sensory continua of individuals are parts of a world-continuum having no independent being of their own apart from it." The causes of changes in my sense-field are "changes within the world-continuum." This appears to mean either that the world consists of individual minds and their sense-fields, or that it consists of these and of sensibilia which do not occur in anyone's sense-field, yet I do not think that Prof Stout would accept either of these alternatives. A psycho-physical theory based on the former alternative would have to be a sort of monadism, such that the *changes in the world-continuum* which determine changes among my sense-data would be changes in other monads. The latter alternative is a form of the Mill-Russell theory. But Prof Stout has explicitly rejected monadism just as much as the Mill-Russell theory on the ground of repugnance to common sense, and I therefore do not see how his final solution is to be reconciled with the common sense he has set out to defend.

AUSTIN DUNCAN-JONES

## Colour Standardisation

*Colour Science · a Handbook for Advanced Students in Schools, Colleges and the various Arts, Crafts and Industries depending on the use of Colour*  
By Dr Wilhelm Ostwald Part I *Colour Theory and Colour Standardisation* Authorised translation, with an Introduction and Notes, by J Scott Taylor Pp xviii + 141 + 13 plates (London Winsor and Newton, Ltd, 1931) 15s

EXCEPT for a historical résumé of the contributions of Newton, Goethe, Schopenhauer, Helmholtz, Young, Maxwell, and Hering, and short descriptions of the tentative efforts at colour arrangement made by other investigators of the eighteenth and nineteenth centuries, this book is purely an exposition of the author's own views on the subject of colour standardisation, and an introduction to his own system. The student of such matters who approaches them through the medium of this book will unquestionably conclude that no one, excepting Ostwald, has paid any attention to them since the days of these early pioneers, and that it is only with the advent of Ostwald's system that colour measurement has become *possible*. This is explicitly stated (pp xiii, 32, and 69), and is implied throughout the whole book.

There are no references to the intensive study which has been devoted to such problems in the United States, Great Britain, and the author's own country within the last twenty years, and no indication is given of the principles which form the common basis of the systems officially adopted at such institutions as the U.S. Bureau of Standards, the National Physical Laboratory, and the Physikalische Technische Reichsanstalt, and employed, with or without superficial variations in minor details, by numerous technical workers in the United States, Great Britain, Germany, and other countries.

It will be evident, therefore, that this book, while it will doubtless be read with interest by those who are already familiar with colorimetric developments but may have found difficulty in following Ostwald's work in German, will give a misleading impression to any beginners who may be induced to regard it as a textbook on colorimetric science.

Prof Ostwald's method of presentation is not likely to appeal to the scientific reader. His style is that of a schoolmaster giving an account of matters concerning which there can be no dispute, it is dogmatic, and therefore unsuitable, where, as in the present case, he is discussing matters on which he is at variance with contemporary workers in the same field. Nowhere is any

experimental evidence offered with sufficient technical detail to enable the reader to appraise its value or check it in his own laboratory. We have to be content with the statement that so and so "withstands this test perfectly" (p. 80), or that "I have found the expected agreement" (p. 138).

Only a brief reference to the main features of Ostwald's theory of colour standardisation is here possible. One fundamental fallacy underlies the whole theory and is responsible for all the special features which distinguish his system. Ostwald claims to have discarded the physical characteristics of the *stimulus*, such as frequency, energy, and luminosity, and to have substituted for these, as the basis of his system of numerical colour specification, the properties of visual *sensations*, including their æsthetic relations, harmonies, etc. In doing so he overlooks the essential nature of every process of *measurement*, and the mathetic impossibility of obtaining by any such process quantitative relations between non-physical things, or between physical things on one hand and non-physical things on the other.

It is now well recognised by every physicist who has given attention to visual problems that every 'colour equation' or 'brightness equation', in whatever nomenclature it is disguised, is a *stimulus* relation. All the experimentally determinable quantities which appear in it are stimulus quantities and cannot be anything else. Ostwald takes as his fundamental relation for the colours of all objects under the same intensity of incident illumination the equation

$$C + W + B = 1,$$

where  $C$  is what he terms the 'full colour' which determines the hue,  $W$  is white, and  $B$  is black. He conceives this to be an analysis of the colour *sensation*. But, whenever we insert *measured* quantities for  $C$  and  $W$ , the equation necessarily becomes an analysis of the *stimulus*. The term in  $B$  then becomes meaningless, since black has no stimulus value and  $(C + W)/1$  is simply the fraction of the incident light which is reflected (or transmitted) by the object. It is equivalent, if the units are properly chosen, to what in present English nomenclature is termed the 'brightness factor' of the specimen. It is a mere photometric ratio of two stimulus intensities. The ratio  $C/(C + W)$  is also a stimulus ratio, and is of the same nature as the ratio which is variously termed, in English literature, 'purity' or 'colorimetric saturation'. The principle is not affected by the fact that instead of employing the easily definable and easily reproducible homogeneous spectral radiations as the hueful

constituents of the system, Ostwald employs the ill-defined and incompletely saturated 'full colours' of his colour circle. If these so-called 'full colours' were properly and unambiguously defined in stimulus terms, an Ostwald specification would be immediately convertible to a specification in terms of dominant wave-length, colorimetric saturation, and brightness factor.

In principle, therefore, the system of colorimetrics embodied in Ostwald's fundamental equation is not new. It follows at once from the application of Newton's law of colour (stimulus) mixture to the Maxwell triangle, and was propounded by Helmholtz in a proposition quoted on p. 22 of the present book, and condemned by Ostwald as having been "the cause of protracted delay in the development of colour science".

The apparent differences of Ostwald's system from previous systems embodying the same principle are all non-essential. The psychological and æsthetic considerations which lead him to base his numerical scales on geometric progressions and give rise to the distinctive features of his nomenclature have no relevance to colour *measurement*, in which stimulus quantities alone can enter. They merely result in confusion of thought and in the absence of proper definition which necessarily results from the apparent determination to avoid calling a spade a spade.

It does not follow, however, that because Ostwald's system of colour specification is merely a disguised form of a well-known and long-established system, which, incidentally, follows directly from the more fundamental 'trichromatic' system, that the practical results obtained by users of Ostwald's methods are sound. It is true that if apparatus were devised to obtain, correctly, the various elements of the Ostwald specification, a perfectly sound and self-consistent system, directly relatable to colorimetric fundamentals, would result, although, in practice, the introduction of the so-called full colours instead of simple homogeneous constituents merely leads to inconvenience. The methods of measurement actually employed by Ostwald are not described in volume 1, and so do not properly come within the scope of this review, but in view of the fact that some of the theoretical conclusions advanced in the present volume are presumably based on such measurements, it is necessary to point out that Ostwald's metrical technique, in which the quantities  $C$  and  $W$  are evaluated by methods of filter photometry, does not in fact give these quantities, but merely an approximation thereto, of more or less crudity de-

pending on the nature of the absorption curve of the specimen under test. This failure of the experimental technique to give a true representation of the fundamental equation is no doubt the cause of these inconsistencies which have been found by those who have carried out proper colorimetric analysis of the Ostwald standards

J GUILD

### Amalie Dietrich, Naturalist

*The Hard Road the Life Story of Amalie Dietrich, Naturalist, 1821-1891* By her daughter, Charitas Bischoff. Pp 317 (London Martin Hopkinson, Ltd, 1931) 10s 6d net

THIS is an intensely human document, not a book of natural history. Amalie Dietrich was the daughter of a leather worker, of Siebenlehn, in Saxony. She was almost uneducated when she married a 'naturalist', an affair of temporary passion on his part. She became his slave, educating herself, learning to collect and mount plants and animals, carting his vasculum and baskets. He lived in the clouds, mostly of his own concert, happy over a new plant which perchance would be called after him. Excursions were made all summer, and in the winter they took the road, visiting town after town, finding out from chemists the addresses of naturalists who might buy their collections. Later Amalie writes "I used to trail all over the country with dear faithful Hector [the dog]! The cart was so heavy and the road often so bad, we had to endure hunger, frost and heat, and ceaseless crushing anxiety as to our daily bread, and you [her daughter]" It is a vivid picture of the collecting craze and of the rivalry that arose out of the work of Linnæus, especially keen in the various State centres of Germany.

This life could not last, and the errant fancy of Wilhelm, her husband, took flight. We need not follow the next years, after which, her reputation as a collector established, she took service under Cæsar Godeffroy. The romance of the Godeffroy Museum, now the property of the City of Hamburg, is well known. Every skipper of this merchant prince was ordered to bring back curiosities from the domains of this "king of the South Seas", whose influence permeated every island group in the Pacific where coconuts were grown, and every beachcomber looked forward to the arrival of his ships. Indeed, in the 'nineties, the writer had more inquiries about Godeffroy than the almost legendary Queen Victoria, his supposed rival. He financed Amalie Dietrich for ten years during which she collected the Queensland region from Brisbane

to Torres Straits and also Tonga. Plants were her speciality, but insects, mammals, birds, native weapons, skulls, and indeed everything, were sent home properly labelled. She loved the collecting and the hard work, the handling and labelling of her specimens, perhaps to-day the most valuable collections secured by any single person.

On her return home, Godeffroy, with characteristic generosity, for thirteen years gave her rooms in his house, close to the beloved museum, and after his death the municipality of Hamburg looked after her. She was still a peasant at heart and in her ways, but she was a genius in her line, and Germany has perhaps a better way of appreciating and making happy such originals as she was. He who sets out to collect can learn much from her story, collecting is not the mere accumulation of specimens, but an art.

### Short Reviews

*Contraception (Birth Control) its Theory, History, and Practice, a Manual for the Medical and Legal Professions* By Dr Marie Carmichael Stopes. New and enlarged edition. Pp xxvii + 487 + 10 plates (London G P Putnam's Sons, 1931) 15s net

IN this new edition of Dr Marie Stopes's treatise on the control of conception it has been possible to exclude a considerable amount of matter of the nature of 'propaganda' which appeared in earlier editions, and to extend those portions dealing with methods and technique, and so to render the book of more service to the medical practitioner. Needless to say, the book deals very fully with all aspects of the subject, and nothing essential seems to have been omitted. It is of interest to find that the records of birth-control clinics so far available establish the fact that the simplest and cheapest technique of all (a rubber cap associated with a chemical spermicide) yields the highest degree of security and reliability.

Dr Stopes naturally deals at length with arguments advanced against the use of birth-control, but we fear she is as one crying in the wilderness, for there will always be persons or bodies who will oppose it on medical or moral grounds. We believe that the argument of opponents respecting the physical harmfulness to the woman of contraceptive measures has been much exaggerated, and that simple measures like those advocated may be pursued without detriment. As regards abstinence versus contraception for the limitation of families, it may be said that in general for a normal couple living together in the intimacy of married life abstinence appears to have a very deleterious effect. The subject has, however, a much wider issue than that of the individual, for many regard the artificial limitation of populations as a measure upon which the salvation of the human race in the future may largely depend. A fuller and wider knowledge of

contraception and all that it may mean for the individual and the race is desirable among medical men that it may be judiciously passed on by them to the general public, and this new edition of Dr Marie Stopes's book will be found to give all the information that may be required

*Board of Education Science Museum Henson and Stringfellow, their Work in Aeronautics the History of a Stage in the Development of Mechanical Flight, 1840-1868* By M J B Davy Pp 115 + 25 plates (London H M Stationery Office, 1931) 5s net

THE experiments of Henson and Stringfellow on mechanical flight were of an exceptionally interesting character, and now that much of their apparatus has been secured for the nation, and placed on exhibition in the Science Museum at South Kensington, it is only fit that whatever is known of the men and their activities should be placed on record. Neither of them was included in the "Dictionary of National Biography", and this record, prepared by Mr Davy and fully documented, will be welcomed by every student of aeronautics wishing to know something of the history of the subject.

Henson was born in 1805 and died in 1888, while Stringfellow was born in 1799 and died in 1883. How they came to collaborate, what experiments they carried out together or separately, and what they actually achieved, are all well told, and the illustrations include not only photographs of their model machines, but also drawings from which it would be possible to construct replicas. If the Aerial Transit Company, launched in 1844 to utilise an invention "which if ultimately successful will be without parallel even in the age which introduced to the world the wonderful effects of gas and of steam", was mainly productive in providing material for the caricaturists, its failure does not detract from the merits of the inventors, whose ingenious and persevering efforts brought them very near to a success which, to-day, we know to have been beyond their reach.

*A Textbook of Physiology* By Prof William D Zoethout Fourth edition Pp 724 (London Henry Kimpton, 1931) 18s net

THE third edition of this "Textbook of Physiology" was reviewed in these columns only three years ago (NATURE, vol 123, p 379; 1929). The fact that a new edition has been called for so soon indicates that the work fills a definite gap in physiological literature. It is a medium-sized textbook, shorter than the number of pages might indicate owing to the size and clearness of the printing. It is intended to present the main facts of physiology in adequate detail, but makes no claim to supplant the larger works. A few references to monographs or reviews are given in each chapter, so that the reader who is interested is put on the track of the literature of different branches of the subject.

The author has taken the opportunity to revise the work throughout, especially the sections dealing with the central nervous system, metabolism, and the endocrine glands, in addition, a number of

new graphs, diagrams, and anatomical illustrations have been added. The application of the facts of physiology to the maintenance of health in man is frequently emphasised. Some paragraphs referring to certain human ailments serve to link the subject with medicine, so that the medical student can realise the importance of his study of physiology for his later clinical work. The book may be recommended to medical students and to others commencing the study of physiology.

*Heredity* By Prof A Franklin Shull (McGraw-Hill Publications in the Zoological Sciences) Second edition Pp xv + 345 (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1931) 15s net

PROF SHULL's textbook presents the essentials of Mendelian heredity with special reference to human problems. It is intended for students, the majority of whom have no biological training and do not intend to specialise in that science, reading genetics as part of a general education. The second edition is bulkier than the first (1926), owing mainly to expansion of the chapters dealing with human inheritance. The absence of any mention of natural selection, either in the chapter on the mechanism of evolution or in the index, is surprising, for the chief problem confronting the Mendelian who sets out to explain evolution is to show how progressive modification of a race, continuing through vast numbers of generations, can be brought about by random mutation, and here the hypothesis of natural selection offers at least a plausible explanation. The recent discussions by Haldane, Fisher, Hogben, and others of the effect of selection on Mendelian populations should receive attention in this context, and would also illuminate the chapter on eugenics.

*Die Gift- und Arzneipflanzen von Mitteleuropa mit besonderer Berücksichtigung ihrer Wirkungen* Von Dr Otto Gessner Pp viii + 348 + 128 Tafeln (Heidelberg: Karl Winters Universitätsbuchhandlung, 1931) 9 50 gold marks

THIS very useful handbook of poisonous and medicinal plants differs from most other books on a similar subject in the arrangement, the balance of matter in the text, and the illustrations. The plants discussed are not arranged according to one of the well-known taxonomic schemes, but under headings of the chief active chemical constituents, such as alkaloids, glucosides, tannins, and etherial oils. Each group is prefaced by a lucid summary of its more important chemical features. Most of the text is occupied by accounts of the species native to or cultivated in central Europe and used in pharmacy or known to be, or suspected of being, poisonous. Under each species, besides a brief botanical description, the active principles are given, and usually a full account of the pharmacology, including symptoms, physiological reactions, and treatment. The work is accompanied by 128 coloured plates, of varying merit, but the majority botanically excellent and several aesthetically noteworthy, and a long index.

## Origin of the Gamma Rays\*

By the Right Hon LORD RUTHERFORD, O M, F R S

IT has long been known that some of the radio-elements emit a penetrating type of X-rays known as the gamma rays. It is clear that these radiations arising from the nucleus of the radioactive atom represent in a sense some of the characteristic modes of vibration of the nuclear structure. The wave-length and quantum energy of many of the stronger lines in the complicated gamma ray spectrum have been determined by different methods, with concordant results. It has been difficult to determine with certainty the origin of this radiation. It was at first supposed that it must arise from the motions of electrons in the nucleus, but in recent years there has been a growing belief that the radiation is connected with the transition of an  $\alpha$ -particle or proton which forms part of the nuclear structure.

It is not an easy matter to distinguish between the various hypotheses, since very little is known about the detailed structure of the nucleus. Fortunately, during the last two years, two different methods of attack on this problem have been developed. The first depends on an analysis of the groups of long-range  $\alpha$ -particles which are emitted in small numbers from radium-C and thorium-C, and the other the analysis of the fine structure shown in the emission of  $\alpha$ -rays from certain bodies. It may be supposed that the emission of a  $\beta$ -particle during a transformation causes a violent disturbance in the resulting nucleus, some of the constituent  $\alpha$ -particles being raised to a much higher level of energy than the normal. These  $\alpha$ -particles are unstable and after a very short interval fall back to the normal level, emitting their surplus energy in the form of a gamma ray of definite frequency. According to the ideas of wave mechanics, in this short interval there is a small chance that some of the  $\alpha$ -particles in the higher levels can escape from the nucleus.

On these views, the escaping  $\alpha$ -particles represent the long range  $\alpha$ -particles observed, and the energy of the  $\alpha$ -particles gives the value of the energy level in the nucleus which it occupied before its escape. Following out these ideas, the long range  $\alpha$ -particles which escape from radium-C have been carefully analysed, using the new electrical methods of counting  $\alpha$ -particles.

Nine distinct groups of particles were observed, and the energies of  $\alpha$ -particles forming each group were determined. The differences of energy between the various groups were found to be closely connected with the energy of some of the most prominent  $\gamma$ -rays in the spectrum, and, in general, the experiments gave strong evidence that the  $\gamma$ -rays had their origin in the transition of one or more  $\alpha$ -particles in an excited nucleus.

It has generally been supposed that in a radioactive transformation all the  $\alpha$ -particles are expelled

with identical speed. This is certainly the case for most bodies, but Rosenblum found that the element thorium-C emitted not one but five distinct groups of  $\alpha$ -particles. This discovery was made possible by making use of the great Paris electromagnet in order to bend the  $\alpha$ -particles into a semicircle. Gamow pointed out that the appearance of such a 'fine structure' in the  $\alpha$ -ray emission should be accompanied by the liberation of  $\gamma$ -rays.

Owing to certain experimental difficulties, it is not easy to obtain a clear-cut decision on this point. Ellis concludes from his experiments that Gamow's view is correct, but Meitner, from similar experiments, reached an opposite conclusion. In view of this difference of opinion, I have made in conjunction with Mr Bowden some experiments to throw light on this problem in another way. Recently Lewis and Wynn Williams found that the actinium emanation emitted two distinct groups of  $\alpha$ -particles differing in energy by about 340,000 volts. It was seen that this observation offered a simple method of testing the theory of Gamow. The emanation was carried by a current of air into a separate chamber and the emission of  $\beta$ - and  $\gamma$ -rays tested directly. It was found that the transformation of the emanation was accompanied by a weak  $\beta$ -radiation and a strong  $\gamma$ -radiation. The experimental results were in good accord with the theory, and thus showed that the presence of a 'fine structure' in the  $\alpha$ -ray emission is accompanied by the emission of  $\gamma$ -rays. At the same time, the results afford strong corroborative evidence that the  $\gamma$ -rays have their origin in the transitions of an  $\alpha$ -particle in an excited nucleus.

It is of interest to consider how far these views can be carried into the region of the artificial disintegration of the elements resulting from the bombardment of certain light elements by  $\alpha$ -particles. In some of these disintegrations it is necessary to assume that the  $\alpha$ -particle can be captured in different energy levels, and that a  $\gamma$ -radiation is emitted as a result of the transition between the two levels. Penetrating radiations have, in fact, been observed in several cases when light elements are bombarded by  $\alpha$ -particles. Some of these cases are of peculiar interest.

## RADIATION FROM BERYLLIUM AND THE NEUTRON

In examining the artificial disintegration of light elements under the action of  $\alpha$ -rays, Bothe and Becker in 1930 noted that beryllium under  $\alpha$ -ray bombardment did not emit protons like boron or nitrogen, but gave out a weak radiation which was more penetrating in character than the  $\gamma$ -rays from radium. The absorption of this radiation in its passage through matter was later examined in detail by Mme Curie-Joliot and M Joliot, and by Webster.

It is usual in experiments of this kind to employ active preparations of polonium on a metal disc as a source of  $\alpha$ -rays. This source is very convenient

\* Substance of the Friday evening discourse before the Royal Institution on March 18

for the purpose, as the results are not obscured by the presence of  $\beta$ - and  $\gamma$ -rays which are so freely emitted from other  $\alpha$ -ray sources such as radium-*C* and thorium-*C*

In examining the absorption of this beryllium radiation by the ionisation method, Mme Curie-Joliot and M Joliot made the striking discovery that hydrogen material, when exposed to this radiation, emitted swift protons. In explanation, they suggested that the protons gained their energy by a radiation recoil in a process similar to the well-known Compton effect, and estimated that the quantum energy of the radiation must be of the order of 50 million electron volts.

J Chadwick, using direct counting methods of great sensitiveness, found swift recoil atoms were liberated not only in the passage of the radiation through hydrogen, but also in other light elements, including helium, lithium, beryllium, carbon, air, and argon. In a letter in *NATURE* of Feb 27, he pointed out that the results in this and other directions were difficult to reconcile with the hypothesis of a quantum of radiant energy of such high frequency. He suggested that the effects observed were not due to a  $\gamma$ -radiation at all, but to the liberation from the bombarded beryllium of a stream of swift uncharged particles or 'neutrons'.

The idea of the possible existence of neutrons, that is, of a very close combination of a proton and electron to form an uncharged nuclear unit of mass nearly 1, is not new to science, but it has been very difficult to find any definite evidence of its existence. I discussed the properties of such a neutron in the Bakerian Lecture before the Royal Society in 1920, and both the late Dr Glasson and Dr Roberts made experiments in the Cavendish Laboratory to test whether neutrons were produced in strong electric discharge through hydrogen, but without success.

It is to be anticipated that a projected neutron would produce little, if any, ionisation in its passage through matter, and would pass freely through the outer structure of atoms. A swift neutron should, however, indicate its presence by the recoil of an atomic nucleus with which it collided. This recoiling nucleus would spend its energy of motion in ionising the gas, and should thus be readily detected by its electrical effect or by the trail of water drops it produces in a Wilson expansion chamber. In some respects, however, the effects produced by a neutron would be very similar to those due to a quantum of high-frequency radiation, and careful experiment is required to distinguish between them.

The velocity of the neutron at the moment of its liberation is estimated to be about  $3 \times 10^9$  cm/sec, or about one-tenth of the velocity of light. By comparison of the velocity of recoil of different atoms, Chadwick finds that the mass of the neutron is about the same as that of the hydrogen atom. In addition, the velocity of recoil of a given atom falls off when the radiation is passed through increasing thicknesses of an absorbing material like lead. This is exactly the behaviour to be expected for the neutron, but not for a high-frequency radiation.

Very valuable information on this problem can be obtained by photographing the effects due to the passage of this new type of radiation through a Wilson expansion chamber. A number of such experiments have been made by N Feather and P I Dee in the Cavendish Laboratory in association with Dr Chadwick. For example, it is to be anticipated that the neutron would occasionally collide with the electrons in its path, and thus give rise to an electron track of maximum length corresponding to twice the velocity of the neutron. This is exactly analogous to the well-known production of  $\delta$ -particles by the passage of  $\alpha$ -particles through gases.

Several such short electron tracks have been photographed by Dee which have about the right length, and for which it is difficult to suggest any other explanation. Feather has obtained photographs of more than a hundred recoil tracks produced in an expansion chamber filled with nitrogen. He has observed another very interesting effect. In addition to the straight recoil tracks, he has obtained photographs of a number of branching tracks which indicate that the nitrogen has disintegrated in a novel way. These branch tracks are believed to be produced by the recoiling nucleus and by some particle which is ejected from the struck nucleus. The identity of this latter particle has not yet been definitely established.

It will take time to analyse the results obtained, and to examine the effects produced in other gases. The peculiar properties of the neutron allow it to approach closely, or even to enter, nuclei of high atomic number, and it will be of great interest to study the effects of such collisions. It is, however, evident that this new radiation has surprising properties, and there is every promise that it may prove an effective agent in extending our knowledge of the artificial disintegration of elements. It will, for example, be of much interest to decide whether the neutron is captured in such disintegrating collisions, or whether it merely passes through the nucleus on which it has such a catastrophic effect.

Mme Curie-Joliot and M Joliot and Dee have independently noted that some swift electron tracks are observed in the expansion chamber. The exact origin and nature of these particles will require careful examination. It is possible that a  $\gamma$ -radiation is emitted from beryllium as well as the neutron. Mme Curie-Joliot and M Joliot found that the radiation from boron bombarded by  $\alpha$ -particles behaved similarly to that from beryllium. It is possible that other elements will also give rise to radiations of this kind.

Whatever may be the final explanation of the interesting facts observed, it is clear that if they are due to a quantum of radiation, we must relinquish the laws of the conservation of energy and of momentum in the production of this radiation and its inter-action with matter. If we wish to retain these laws, the neutron hypothesis seems the only alternative. In any event, it is evident that these new discoveries have opened up a new region of research which is of great interest and promise.

## Index Londinensis \*

WITH the issue of vol 6 of "Iconum Botanicarum Index Londinensis" or, for short, "Index Londinensis", the publication of this great work has been completed. Notices concerning the several volumes as they appeared will be found in earlier issues of NATURE (Jan 11 and April 5, 1930, April 18, 1931). It seems now to be the time for a comprehensive survey of the work, setting down its aims, its bearing on botany, and the development of illustration as an auxiliary for the botanical author, and, last but not least, the claims for a rational continuation of it.

When, nearly fifty years ago, Darwin provided for the publication of a catalogue of the names of the species of flowering plants, with references to their places of publication—a catalogue which has become familiarly known as the "Index Kewensis"—a step was taken which freed the taxonomist of an immense amount of labour and drudgery with one stroke. At the same time it protected him against overlapping and confusion, and guaranteed the consolidation of a widely scattered literature which before long would have become a very serious hindrance to progress. It is, in fact, difficult to visualise how botanical taxonomy could progress without such assistance as is afforded by the "Index Kewensis".

The basis of the records of this catalogue were descriptions, some complete, but many incomplete in widely varying degrees. Of these not a few were accompanied by illustrations or references to illustrations, intended to supplement the description or to support it in the most concise and comprehensive form possible by picturing the plant as a whole or essential parts of it. It is true some of these illustrations, though not indicated as such in the "Index Kewensis", were implicitly put on record by it. However, a much greater number of illustrations of the same order was contained in the pictorial literature, which under some disguise existed already or later grew up in the course of the general progress of taxonomy and its sister branches of morphology and applied botany. An attempt to catalogue the illustrations of flowering plants and vascular cryptogams was made by G. Pritzl in his invaluable "Iconum botanicarum Index locupletissimus", which appeared in 1855 and was supplemented by a second volume in 1866, but this "Index" was avowedly incomplete and for the present-day student very much out of date.

The need for a more comprehensive and up-to-date "Iconum Index" was therefore as pressing as it was undisputed. The difficulty of satisfying it was in the magnitude of the work and the expense which its execution entailed. It was evident from its compass that it could only be

undertaken at one of the few great centres of taxonomic botany and on the strength of an organisation which guaranteed the maximum of completeness, and at the same time a speed of execution that prevented its becoming long out of date before it was finished, whilst the material means required for it were such as to preclude private enterprise. Only an institution wealthy, far-seeing, and generous could risk the outlay, which was bound to be unremunerative from the commercial point of view. The institution was found in the Royal Horticultural Society of London, which rose to the occasion, providing the money for the preparation of the manuscript and securing the co-operation of the delegates of the Clarendon Press, Oxford, who took upon themselves the risk of printing, whilst the Royal Botanic Gardens, Kew, afforded all the facilities at their disposal, housing the staff and granting full use of the Library. Other institutes all over the world also lent their help when occasion required.

Attention may be directed to two features of the "Index". They concern the selection of illustrations and the correlation of the records in so far as they are affected by the conflicting nomenclature, which in the past resulted from the largely ill-organised labour of the taxonomists as a body. There is clearly demonstrated an endeavour to include as many illustrations as possible, wherever they were connected with a scientifically established name, irrespective of their often disputable claim to perfection and completeness. Also homonyms of genera and species have been sorted out and an elaborate system of cross-references for synonymous genera has been introduced. Necessarily a wide field of independent investigation has to be left open to the student, but even so much has been achieved that will save time and lead to literature which otherwise might have been ignored.

The importance of adequate illustration need not be stressed. It is self-evident, and there is the less excuse for neglecting it as a corollary to description and explanation, as the methods of illustration have been much improved, multiplied, and deprived of costliness during the last half century. If it should be argued that they still add much to the expense of publication, it should also be kept in mind that the insertion of illustrations allows in many cases the cutting down of the descriptive text, and also that illustrations may, as is indeed frequently done, be loaned from other works, a practice which will be greatly facilitated by reference to the pictorial treasure-store registered in the "Index Londinensis".

Reviewing the records of the "Index", one cannot help being struck by the largely haphazard method of illustration in taxonomic works, a vast number of genera and species being still very inadequately illustrated, whilst many others are over-illustrated. With the "Index" as a readily accessible basis it may be hoped that the innumerable

\* "Index Londinensis to Illustrations of Flowering Plants, Ferns and Fern Allies, being an emended and enlarged edition continued up to the end of the Year 1920 of Pritzl's Alphabetical Register of Representations of Flowering Plants and Ferns compiled from Botanical and Horticultural Publications of the XVIIIth and XIXth Centuries". Prepared under the Auspices of the Royal Horticultural Society of London at the Royal Botanic Gardens, Kew. By O. Stapf. Six vols (Oxford: Clarendon Press, London: Oxford University Press, 1931) 105s. net each volume.

gaps will now be gradually and methodically filled and redundancies avoided

So far, "Index Londinensis" covers the period 1753-1920 (inclusive). The earlier literature has been drawn upon only in cases where post-Linnean interpretations have lifted it into the reach of scientific nomenclature. Future studies may give occasion for further additions from this, in many respects, valuable field of botany. However, the gap left by the upward limitation of the records to the year 1920 is far more serious. More than ten years of intense activity have now elapsed. When the original issue of the "Index Kewensis" was completed, its continuation by quinquennial supplements was at once insisted upon and carried out, and their discontinuation could not now be considered, and similar consideration should be given in the case of "Index Londin-

ensis". It is already looked upon as the indispensable companion of the "Index Kewensis", and we hope it will remain so. The Royal Horticultural Society has authorised the compilation of a Supplement, intended to take in the pictorial literature for the years 1921-1935 (inclusive), and to be published by the end of 1936 or early in 1937, and it has made an initial grant for one year. The work on the supplement was begun early in 1931 and has so far resulted in a collection of more than 30,000 references, which are now accessible to the student in the Index-room of the Herbarium at Kew. It remains, therefore, to secure the guarantee of such further funds as will be required for the uninterrupted continuation of the work on the basis of, and in conformity with, the main issue, and it is most desirable that provision for this should be made without delay.

### Atmospheric Pollution\*

THE seventeenth report on atmospheric pollution issued by the Department for Scientific and Industrial Research records investigations made in Great Britain in the year preceding March 31, 1931. Observations show that the solid matter deposited from the air in twelve months in 42 towns ranges from 550 tons per square mile at one station in Lancashire down to 72 tons in Leicester, the average being more than 200 tons. Generally the observations show a reduction, especially in the sulphates, presumably due to industrial depression and reduced fuel consumption. In London, for some reason, this is not so, and some increases in atmospheric pollution are recorded.

Indeed, the report does not flatter London, which apparently will continue to have its fogs, and the records of suspended impurities do not support the current belief in the decline in the number of smoke fogs. Charing Cross is one of the worst spots, and the amount of smoke haze seems greatly to exceed that of many industrial centres, where the atmosphere by comparison is clean.

The most remarkable records come from Coventry, where on no single day was a smoke haze recorded. Now, Coventry is a large city, highly industrialised, and the circumstances therefore deserve close scrutiny. The Medical Officer advances several reasons to account for this. Coventry is not congested, and has rural surroundings without obstruction to hinder the scavenging action of the wind. The factories are on the outskirts and freely use electricity for power and gas for the heat treatment of metals. Thus there are few sources of industrial smoke, and no special smoke inspection is necessary. Moreover, the use of gas is almost universal in the kitchens there.

It may be urged, however, how will this help in the smoky cities where the heavy trades are practised? For these, the smoke laws have

always been lenient and have made no restriction on the emission of black smoke, because of the dogma that steel must be heated in a smoky furnace atmosphere. This should no longer be accepted without challenge. After protracted investigation of the influence of atmosphere on the scaling of steel, Prof. J. W. Cobb and his collaborators at the University of Leeds could not find evidence to support this belief. Indeed, no fuel seems more suitable in this respect for heating steel than a producer gas made from a high temperature coke. Experienced men in the Sheffield trades are not disposed to contest this conclusion, which, if valid, destroys the 'divine right' of the heavy trades to use smoky furnaces, however convenient it may be to do so in practice. Again, steel makers have no objection to using coal gas if the price is right. Any doubt about this is dispelled by a journey up the Ruhr Valley in Germany, where coke oven gas is freely used. The comparative cleanness of the atmosphere and the towns there makes a remarkable contrast with corresponding areas in England.

An observant traveller going north from Sheffield may first be shocked by the gross atmospheric pollution he will observe, and in a few minutes amazed by the sight of great flares of coke oven gas—a smokeless fuel—burning to waste. True, this is in process of remedy by the organisation of the South Yorkshire Gas Grid, which now has legal sanction. In general, the law hinders rather than helps the spread of gas-heating in industry, and politicians obsessed with the organisation of electrical supply have done little to assist. In this direction smoke abatement organisations might use their influence.

The report records a study of the proportions of sulphur acids in the London atmosphere, where in foggy weather the quantity of sulphur dioxide may reach one volume per million, although normally it is much less. The work indicates the growing interest in sulphur impurities, the importance of which was emphasised by the tragedy of Liège last winter. It is unlikely that the

\* Department of Scientific and Industrial Research. The Investigation of Atmospheric Pollution. Report on Observations in the Year ended 31st March 1931. Seventeenth Report. Pp. vii+110. (London: H.M. Stationery Office, 1931.) 5s. 6d. net.

absolute quantity of sulphurous impurities is increased by the concentration of power generation in central stations, but the consequences may become more serious for people and property in the immediate neighbourhood. On the other hand, this concentration of power production facilitates the application of processes for the desulphurisation of flue gases. The London Power Company claims to have worked out a practicable process by the use of lime water. Recent patent literature describes a process based on the use of ammonia, which has the merit of producing no intractable liquid effluent. Moreover, ammonia

to-day, in the form of gas liquor, is cheap and freely available. It seems fitting that the alkali from coal should be used to neutralise its sulphurous products. However, it can scarcely be doubted that the atmospheric pollution by sulphur due to boiler furnaces can be largely removed when necessary steps are taken.

The report is a voluminous document, containing much interesting matter, both descriptive and tabular. One puts it down with regret that, together with so much knowledge of the problem and its remedy, there should be so little progress towards amelioration. H J HODSMAN.

### Obituary

DR E H GRIFFITHS, F R S

DR E H GRIFFITHS, formerly principal and professor of physics in the University College of South Wales and Monmouthshire, died, after a long and painful illness, on March 3, at his residence in Cambridge, in his eighty-first year.

Dr Griffiths went to Cambridge from Owens College, Manchester, and entered at Sidney Sussex College. He took an ordinary degree in the Applied Science Special in 1873, and shortly afterwards started work as a private tutor, becoming associated with Dr Campbell, a well-known coach for the examinations in law, and at a later date with the late Mr C T Heycock. In this work he was very successful, pupils of Griffiths and Campbell usually did well in their examinations, and he was soon recognised as one who could be trusted to do his best for a lame dog.

It was not until much later (1889 or 1890) that it was realised that there was a physicist of very marked ability working almost in solitude at the Sidney Laboratory, where Neville and Heycock had been engaged on their well-known metallurgical researches. It was about this time that I first met him, when he came to the Cavendish Laboratory to ask me to standardise a resistance box he was then using—I was in charge of the British Association standards of resistance—and I then learned that he proposed to make what appeared to be a very ambitious attack on the determination of Joule's equivalent, employing the electrical method. To quote his own words from a later paper: "I commenced this work in 1887, and the general principle on which I proposed to proceed was that of eliminating the effects of conduction, radiation, etc., rather than of ascertaining the actual loss or gain due to these causes."

Griffiths' time during the next two years was devoted to preliminary work, difficulties inherent in the mercury thermometer led him to investigate platinum thermometers and the measurement of platinum temperature as introduced by Callendar in 1886.

The platinum temperature  $pt$  at any temperature  $t$  is obtained by measuring the resistance of a wire of platinum. Callendar showed (*Phil Trans Roy Soc*, A, 161, 1887) that the difference,  $t - pt$ , could be expressed in terms of  $pt$  by a formula involving

a single coefficient, and at first supposed that this coefficient was the same for all wires of reasonably pure platinum. Griffiths in his paper (*Phil Trans Roy Soc*, A, 43, 1891) proved that while the formula held with great accuracy, the coefficient varied appreciably from wire to wire—no wire was absolutely pure—so that to standardise a platinum thermometer, a third temperature in addition to the freezing and boiling points of water was required, and in a further paper (*Phil Trans Roy Soc*, A, 119, 1891) Callendar and he communicated an accurate determination of the boiling point of sulphur, and described apparatus for making use of that temperature as a third standardisation point. The platinum thermometer thus became a reliable instrument. In this way means for the accurate measurement of the temperature of the calorimeter were provided, and his real work—the determination of the mechanical equivalent of heat,  $J$ —could begin, at first in the Sidney Laboratory. Cambridge trams soon made that impossible, and a special building was erected in his own garden.

The investigation described in his paper, "On the Value of the Mechanical Equivalent of Heat" (*Phil Trans Roy Soc*, A, 361, 1893), still constitutes the standard determination by the electrical method. It may be useful to quote the values of  $J$  deduced from the results of various experimenters by Griffiths himself in the "Dictionary of Applied Physics", vol 1, 493, 1922, when reduced to the same units and on the assumption that the e m f of a Clark's cell is 1.432 volts.

#### CAPACITY FOR HEAT OF WATER AT 20° (OF THE HYDROGEN SCALE)

|                            |                         |
|----------------------------|-------------------------|
| Rowland, 1878              | 4 182 × 10 <sup>7</sup> |
| Griffiths, 1893            | 4 184 × 10 <sup>7</sup> |
| Schuster and Cannon, 1894  | 4 182 × 10 <sup>7</sup> |
| Callendar and Barnes, 1899 | 4 181 × 10 <sup>7</sup> |
| Mean                       | 4 182 × 10 <sup>7</sup> |

Any uncertainty in his result depends mainly on the uncertainty attaching to the electrical units of his day, and for the values of these he was dependent on the work in progress at the time at the Cavendish Laboratory.

For some years after this, Griffiths took an active part in discussions at the British Association and

elsewhere relating to electrical and thermal units. He became a fellow of the Royal Society in 1895, and in the same year joined the Electrical Standards Committee of the British Association. A provisional definition of the calorie as the heat required to raise a gram of water from  $9.5^{\circ}$  to  $10.5^{\circ}$  on the scale of the hydrogen thermometer, adopted at the Liverpool meeting in 1896, was the outcome of the replies sent by some twenty prominent physicists to a letter in which he urged the importance of international agreement as to thermal units.

On Griffiths' acceptance, however, in 1901 of the post of principal of the University College of South Wales and Monmouthshire, active experimental work ceased, pending the erection and equipment of a research laboratory. Administrative and educational duties absorbed his time for a number of years. At a later date the laboratory was erected, and along with Dr. Ezer Griffiths he published (*Phil. Trans. Roy. Soc., A*, **213**, 119, and **214**, 319, 1914) two papers dealing with the capacity for heat of metals over the range from  $120^{\circ}$  abs. to  $400^{\circ}$  abs. Included in the latter paper

is a comparison of their results with those given by various formulæ designed to represent consequences deduced from the quantum theory. The method employed was in every case electrical, utilising very effectively the experience gained in Griffiths' original work on *J*.

During the tenure of his principalship, Griffiths held many important positions; he was vice-chancellor of the University of Wales on three occasions, and served as president of two sections of the British Association. On his retirement in 1918 from his university offices he returned to Cambridge, and shortly afterwards became treasurer of the British Association. The death of Mrs. Griffiths the same year left him a changed man; she had been an invalid for some time, but much was hoped from a quiet life at Cambridge. However, this was not to be, and in the course of a few years Griffiths became a complete cripple, maintained alive, and to visitors happy and contented, by the care and attention of his nurse. His work was recognised by his College by his election as a fellow in 1897, and at a later date as an honorary fellow.

## News and Views

### Award of Duddell Medal

THE Duddell Medal of the Physical Society was presented to Prof. C. T. R. Wilson, Jacksonian professor of natural philosophy in the University of Cambridge, at the annual general meeting of the Society, held on March 18. Prof. Wilson's contributions to physical science fall mainly into two groups: those associated with the investigation of the tracks of ionising particles on one hand and the investigation of atmospheric electricity on the other. The word 'cloud' is the appropriate symbol of both groups. In 1895, Prof. Wilson discovered that clouds could be produced in a super-saturated atmosphere freed from the dust particles, which the earlier experiments of Aitken indicated as an indispensable condition for initiating condensation. Two definite critical expansions corresponding to fourfold and eightfold super-saturation were found. Using an X-ray tube which had been made by Mr. Everett in the Cavendish Laboratory in 1895, Prof. Wilson observed again the formation of fog when the expansion was between the critical values. Further experiments revealed that purely ionising agents all produced nuclei on which water condensed when, and only when, the super-saturation exceeded the lower critical limit. The condensation nuclei were shown to be ions by their behaviour in an electric field. These investigations were applied by J. J. Thomson, H. A. Wilson, and R. A. Millikan to the measurement of the ionic charge; it was also shown that the degree of super-saturation required to cause negative ions to grow into visible drops leads to the value  $4.9 \times 10^{-10}$  e.s.u. for the elementary charge.

So long ago as 1911 Prof. Wilson devised an expansion apparatus with means of instantaneous illumination of the cloud particles for the purpose

of photographing them. On the path of a primary X-ray beam he observed a large number of little patches of cloud representing the paths of very short cathode rays; these are now known to be the tracks of the recoiling electrons in the Compton effect. The final improvement of the expansion method consisted in taking stereoscopic pictures of clouds, and Blackett in particular has obtained photographs of the tracks from collisions of particles with atomic nuclei, indicating the atomic disintegration thereby produced. The work of Prof. Wilson in atmospheric electricity has opened up new and profitable fields of inquiry. His method of studying rapid changes of the earth's electric field, which is characterised by the experimental elegance evident in all his work, has led to a great increase in our knowledge of the electric fields associated with thunderstorms. His view that the earth's electric charge can be attributed to the action of thunder and shower clouds, the charges of which send negative electricity into the ground in sufficient quantity to balance the dissipation caused by the positive ion current constantly flowing to the ground, is generally accepted.

### Protection of Beneficial Insects

WHILE special laws for the protection from wanton destruction of birds useful in agriculture exist in most countries of the world, parasitic and predaceous insects which are equally, and often much more, beneficial than birds remain unprotected. The main reason, of course, was that there was no need of such protection, but recently an interesting situation arose in Mauritius. A scoliid wasp, *Tiphia*, was introduced into that island from Barbados as a means of checking the beetle *Phytalus smithi*, one of the worst

pests of sugar-cane Colonies of *Tiphia* were successfully established in several places, and the wasps began to spread, doing very useful work in the control of *Phytalus*. The beneficial effect of wasps was soon appreciated by sugar planters, who became very eager to secure the parasites for their own plantations. As a result, mass capture of the wasp and even a regular trade in them developed to such an extent that the carefully elaborated plans for a gradual establishment and spread of the parasite were in danger of being overthrown. In order to prevent this an ordinance has just been issued by the Government of Mauritius providing for the protection of any insect declared to be beneficial, and forbidding anyone to kill, injure, or molest any such insect. The declaration of an insect as beneficial rests with the Director of Agriculture, who is empowered to make surveys of private lands in order to ascertain the presence and the quantity of beneficial insects available for capture and distribution. The ordinance can be regarded as a *de jure* recognition of biological control of insect pests.

#### Federal Council for Chemistry

IN the report for 1931 of the Federal Council for Chemistry, the objects and constitution of the Council are defined with greater precision than heretofore. The objects are to foster and advance the scientific interests of chemistry in all its branches, and to that end (1) to represent the views of British chemists both nationally and internationally, (2) to co-operate with those bodies in Great Britain and the British Empire representing the science of chemistry and to co-ordinate their scientific activity, (3) to enter into scientific relations and co-operate with similar bodies in other countries, and, in particular, to act as the representative of the British associations of chemistry in the International Union of Chemistry. The report states that a sum of £1642 was collected as the contribution of chemists and the chemical industries towards one-fifth of the estimated cost of the Faraday Exhibition in 1931. The committee appointed to consider the question of forming a British chemical standardising body having reported in favour of participation in the new British Standards Institution, unanimous approval of this course has been expressed by the Council. After consideration of the report of the Bureau of Chemical Abstracts on the memorandum submitted by Sir Frederic Nathan advocating the establishment of an international system for abstracting and indexing chemical literature, the Council has reaffirmed its previous decision that the system at present in use in England is satisfactory. Under the heading of international affairs it is announced that the ninth International Congress of Pure and Applied Chemistry and the eleventh Conference of the International Union of Chemistry, which were to have been held in Madrid in April 1932, have been postponed to a more favourable time. The report of the discussion on the chemistry of the carbohydrates held at Liège in 1930 has been issued in separate form, and can be obtained from the Société de Chimie Industrielle (50 fr). During the year 1931

Russia was admitted an adherent organisation of the International Union of Chemistry.

#### Tropical Medicine and Hygiene

THE PRINCE OF WALES opened Manson House, the new headquarters in Portland Place, London, W., of the Royal Society of Tropical Medicine and Hygiene, on March 17. The premises will perpetuate the memory of Sir Patrick Manson, a pioneer in the science of tropical medicine. His Royal Highness pointed out that one of the great obstacles to the development of tropical countries is not so much the climatic conditions but the diseases which are prevalent in them. In spite of this, however, great progress has been made in the study of tropical diseases during the last thirty years. This progress has been due chiefly to the pioneer investigators who devoted their lives to the study of tropical diseases and medicine on the spot, thus saving the lives of hundreds of thousands of the inhabitants of the tropics, not only European but also the native population. One serious consideration at present is the increase in facilities for the spread of disease brought about by the improvement in communications. This problem must be attacked by the investigation of collected pathological material and the establishment of centralised research to help other centres in the investigation and control of disease. In Manson House, discoveries, experiences, and opinions of workers in tropical lands can be pooled for the help of those who will have to face similar problems in the future.

#### Climate and Soil Physics

DR B. A. KEEN, assistant director of the Rothamsted Experimental Station, delivered the G. J. Symons memorial lecture before the Royal Meteorological Society on March 16, his subject being "Soil Physics in Relation to Meteorology". Dr Keen introduced his subject with a description of the different soil types found in different climatic zones. In soil temperatures, the porous and moist nature of soil produces special effects. In particular, the downward percolation of water appreciably reduces the loss of heat from the soil. A full account was given of recent investigations at Rothamsted on the movement and distribution of water in the soil. It was shown that such movements are much less, both in amount and extent, than previously supposed. Water which has reached a depth of about six feet in the average soil is not drawn back to the surface again by evaporation. Many of the farmers' and gardeners' cultivation operations were at one time supposed to conserve this sub-soil water for use by plants, but the explanation has now to be sought for in other directions. The lecture concluded with a review of the development of cultivation implements, from the rudimentary form of a pointed stick, which merely stirred the ground, to the wide range of different types now in use.

#### The Talkatome Home 'Talkie' Equipment

HOME film projectors were popular a few years ago, but apparently silent films are becoming out of date. A demonstration was given by the British Talkatome, Ltd., at their offices at Wells Street, Jermyn

Street, London, S W 1, on March 16, of a sound apparatus for home use. The device consists of a synchronised turntable attached to the projector by a flexible drive. A special sound disc is used in conjunction with the film, and this is placed on the turntable. An electrical pick-up carries the gramophone needle, which is connected to a loud speaker either by the user's radio set or alternatively by a special amplifier. The makers have prepared 'a library of films, including comedies and travel and educational films. The device shown worked quite satisfactorily, and the operation of the equipment is simple. In some cases it might be useful in colleges and schools. The turntable is listed at twenty-five guineas, and the hire of a film from the library is 10s.

#### Witchcraft on the Gold Coast

THE Christian Council of the Gold Coast, a body consisting of representatives of all denominations, of which the Anglican Bishop of Accra is chairman, has taken the unusual course—not, however, without precedent in spiritistic circles—of issuing a challenge to witchcraft. The Council has published a notice in the local press that it is prepared to pay the sum of £10 to any person who, within the term of six months from date, will either 'eat' a papaw, or some other fruit selected by the Committee, at a distance of five yards, without coming into physical contact with it, or extract from a sealed box, without breaking the seal, an article deposited in it by the Committee, or transform himself into any beast, bird, or creeping thing. All these operations are among the powers attributed to the local witches. The Council, in making this challenge, is careful to point out that while many innocent persons are put in great terror by their fear of witchcraft, the harm from it is due not to the powers of witchcraft, but to their fear. Even with this proviso, however, the Council would appear to have been unsuccessful in its attempt to avoid criticism. Objection has been taken to its action on the ground that it constitutes 'witch-finding', and as such is contrary to a local ordinance.

EXTRACTS from the local press criticising the Council are quoted in an article describing the situation at Accra, which appeared in the *Manchester Guardian* of March 15. The Council is recommended to abstain from meddling with witchcraft, and as it does not affirm or deny the belief, it is advised "to leave the Devil alone". Apparently the Council takes its stand on precedent, for it recalls that in the last hundred years the power of 'fetish priests' has been broken in this manner on many occasions. The action of the Council is directed against 'witch-finders' as well as the witch. Some idea of the conditions with which the churches have to deal may be gained from a case quoted from the *Vox Populi*, a local journal, of Feb 20, which reports the 'finding' of a witch, who was charged with killing the child of a sister. When the dead child was placed on her lap, a snake fell from her body. This was taken as proof positive of her guilt, and the woman had to be conveyed away secretly to save her from popular vengeance.

No. 3256, VOL 129]

#### Prehistoric Society of East Anglia

AT the annual meeting of the Prehistoric Society of East Anglia, held at Norwich on Feb 29, Mr J. Reid Moir was elected president. In a paper on the evolution of the rostracarnate and hand-axe in north-east Ireland, Mr J P T Burchell described the geological conditions under which specimens he exhibited were collected. Mr J Reid Moir reviewed the typological evidence of the exhibits, showing that the line of evolution from ancestral eolithic forms and the technical methods of flaking used were identical with those in the lower palæolithic industries of widely separated regions. Dr Mur Evans exhibited a fine bone harpoon from the North Sea bed, deeply peat-stained and similar to the two examples from Holderness now in the British Museum. The specimen came from a large mass of 'moorlog' dredged up between the Leman and Ower sandbanks, about thirty-five miles east of Happisburgh lightship, by the trawler *Colinda*. Mr M C Burkitt accepted the harpoon as clearly of Maglemose type. The specimen has been presented to the Norwich Museum.

#### Fungicide for Oat Seed

EXPERIMENTS carried out at the North of Scotland College of Agriculture, at Craibstone, in 1931, clearly demonstrate the value of dressing oat seed with 'Ceresan', for on an average the yield of grain was 6 cwt and the yield of straw 8 cwt per acre higher on the treated than on the untreated plots. Ceresan is a mercuric compound in the form of a dry powder, which, when mixed with the seed, kills any fungi that may be adhering to the grain. Thorough mixing is essential if the treatment is to be successful, and special machines are now on the market for the purpose. An old churn, however, has been used at Craibstone with very satisfactory results. Mixing on the floor with a shovel is not recommended, partly on account of the difficulty of obtaining a sufficiently thorough mixing by this means, and partly because of the poisonous nature of the compound and the consequent risk of danger to live stock. Care is therefore needed in handling the powder, and if large quantities are being used, it is advisable for workmen to cover their noses and mouths as a precautionary measure. Five ounces are required for every hundredweight of seed, the cost, exclusive of labour, working out at less than one shilling per acre. Although a good stand of oats, such as was obtained on the plots where the seed had been treated, is eminently desirable, too thick a crop is liable to suffer from lodging, and it seems possible that a saving of seed could be effected if Ceresan treatment were carried out. This and other points of importance, such as the influence of weather conditions at harvest on the effectiveness of the treatment, etc., will be investigated in the experiments which are being continued at Craibstone in the present season.

#### Submerged Canyon of the Hudson River

SCIENCE Service has issued a summary of a recent United States broadcast talk on hydrographic matters, by Lieut.-Comm R R Lukens, of the United States

Coast and Geodetic Survey Among the various interesting topics dealt with, is the remarkable submerged canyon of the Hudson River, about fifty miles at sea off the entrance to New York Harbour. This great gorge, approaching in magnitude the Grand Canyon of the Colorado, is at one place more than 2400 ft deep, and three miles wide from rim to rim, it is about twenty miles long, and at its opening spreads out fan-like. It is of use during fog, as a 'seamark' for vessels equipped with sound-echo apparatus. Springs welling up in the sea are also described, both water springs and oil springs. One of the former, off the Florida coast, sends up millions of gallons of fresh mineral water from a hole about 25 ft in diameter and 70 ft deep in the ocean bed, itself 50 ft deep, the water springs up with considerable force, so that it is difficult to hold a boat over it, and it has a sulphurous smell. Elsewhere, off Alaska, the sea-bottom sounding lead, 'armed' with tallow, shows gold dust as a bottom characteristic, but the depth is too great to permit of dredging. Other remarkable ocean features off Alaska are pinnacle rocks, often extending to within a few feet of the surface, which are the cause of many shipwrecks and a submarine volcano, rising from a depth of nearly 6000 ft, which throws up islands and blasts them again with violent explosions, nearly every year witnessing some change in the appearance of the island.

#### Preservation of Chillingham Cattle

THE appeal, to which reference has been made (*NATURE*, Feb 13, p 241), has now been issued by the Zoological Society of London. Recognising the particular interest of the famous herd of white park cattle at Chillingham Castle, and the impossibility of its maintenance, under present financial conditions, by the owner, the Earl of Tankerville, the Council has taken a lease of the Park for seven years at a rental of £500 annually. Of this sum the Council has promised to contribute £100 annually for the seven years, and it appeals, through the three Trustees appointed for the purpose, for assistance in raising the balance required. The cattle herd, which has been enclosed for many centuries, now consists of forty-four animals. It has always been left to follow its own devices, so that annually a master bull fights his way to supremacy, and the retiral of the cows to calve in the woods, where they conceal their young for nearly a fortnight, recalls the habits of the wild extinct ox, or urus, which inhabited prehistoric Britain. The cattle are so wild as to be unapproachable, but arrangements have been made whereby subscribers to the fund may have entry to the Castle grounds and access to a safe place from which the herd may be viewed. Donations or annual subscriptions should be sent to the Secretary, Zoological Society, Regent's Park, London, N W 8, marked "Chillingham Cattle Fund."

#### Future Methods of Charging for Electric Supply

SIR JOHN BROOKE, vice-chairman of the Electricity Commissioners, at a conference on electric light in

architecture, organised for architects by the Lighting Service Bureau, gave an interesting address on the future charges for electricity in London. He pointed out that the aim of the Commissioners is to secure a reasonable uniformity of charge. They have chosen as a basis the two-part tariff—frequently known as the telephone system. The fixed charge is based on the floor area that has to be lighted, and they have devised a scheme for calculating this area. They suggest alternative schemes based either on the number of rooms or the rateable value of the house. In addition to the fixed charge, there is a low running charge made for the energy consumed, which is registered by the meter. He said that the tariff was not popular at first and was not generally accepted. Business men accustomed to dealing with problems of overhead charges and running costs considered it perfectly equitable that everyone who has electricity on tap should pay, in the first place, his share of the capital charges. In five years' time there will be everywhere available—if not compulsory—a two-part tariff. This is of great importance, because in considering the relative costs between minimum lighting, adequate lighting, and that generous scale we should call proper lighting, we have only to reckon on the additional running cost per unit. In the future these additional units will not cost 4d, 6d, or 8d, but will cost  $\frac{1}{2}$ d, 1d, or  $1\frac{1}{2}$ d. The reasonable anticipation that tariffs of this nature will be available in a few years' time, with a steady tendency to reduce the running charge to  $\frac{1}{2}$ d a unit, as it is in several districts in the neighbourhood of London, will obviously popularise the use of electricity for many purposes from the radio receiver to the vacuum cleaner, and make necessary the introduction of many outlet points when designing the electric wiring of a house.

#### Institution of Mechanical Engineers

THE Report of the Council of the Institution of Mechanical Engineers for 1931 states that the total membership of the Institution now stands at 11,161, an increase of 155 on that of 1930. The losses by death numbered 103, among the deceased members being Prof Archibald Barr, Sir Trevor Dawson, Sir Charles Parsons, Sir A J C Ross, and Sir Thomas Stanton. There are now eight branches of the Institution in the provinces and one in South America, and four graduates' sections, all of which have their own programmes of papers. Research work is being continued on alloys, cutting tools, marine engine trials, welding, wire ropes, and other subjects. The Institution has representatives on many boards and committees, including the Royal Society's committee for founding a memorial to the late Sir Charles Parson's. A large number of candidates were examined in England, Scotland, and Ireland for the national certificates and diplomas in mechanical engineering, and the first diplomas were issued for officers of the Royal Air Force, the examination being held in conjunction with the Board of Education and Air Ministry. The Report contains particulars of the awards made for papers read, full details of the finances of the Institution, and records the receipt of gifts, which include a replica of the memorial tablet to George Stephenson at Wylam,

a portrait of the late Sir John Thornycroft, and a commemoration medal of the late Prof. Auguste Râteau

#### Standardisation of Electric Frequency in Paris

ONE of the difficulties in connexion with the nationalisation of the British system of electric supply is the fact that many large systems are using a different frequency of supply from the chosen standard of 50. The discussion, therefore, on the standardisation of the frequency of electricity supply in Paris, held at the Institution of Electrical Engineers on Feb. 29, was a timely one. P. Rieumer exhibited a film which showed clearly how rapid the conversion had been. The Paris area extends in a circle of about thirty miles in radius around Paris. Before the War it was supplied at four different frequencies by various undertakings. In 1919 it was decided to build large modern steam-generating stations in Paris and connect them with a 60 kilovolt ring main around the city, which was also connected by transformers to the hydro-electric stations of the Central Plateau through the 120 kv and 220 kv. mains. In addition, it was decided to create a national network at a frequency of 50 which could be converted into direct current at the highest possible voltage for the electrification of the railways. Instead of having a grid round the country as in England, connected with large and efficient generating stations, France has a series of lines radiating from the principal centres of consumption. In Paris the conversion of the two-phase to direct current is carried out by rotary converters and mercury arc rectifiers. On the 25 frequency network all motors are replaced either by new or second-hand motors having twice as many poles. On the 41½ frequency network the motors have been unchanged, but the mechanical units to which they are coupled have been adapted to work at a 20 per cent increase of frequency. Luckily the motors were originally manufactured in 50 frequency frames, so it was only necessary to speed them up to the figure for which they were originally designed. Difficulty was experienced in converting small motors such as those used for calculating machines and similar apparatus.

#### Books for the Blind in the United States

THE Report of the Library of Congress, Washington, D.C., for the year ending June 30, 1931, is a volume of 463 pages, which includes a review of the activities of its various divisions and gives much interesting information regarding the books and manuscripts acquired during the previous twelve months. The total number of books and pamphlets is now 4,292,288, as against 4,103,936 in June 1930. "A new responsibility imposed upon us by legislation at the last session", says the report, "concerns the supply of books (in embossed type) for the blind." It is embodied in an Act approved on March 3, 1930, which makes an appropriation of 100,000 dollars to provide books for the use of adult blind residents of the United States. For some time past the Library has done notable work for the blind, and now has a collection of 22,655 books, periodicals, music, etc., mainly in Braille. During the year 1930-31 there

were 3359 registered borrowers and 52,222 issues of books, etc. Of this number, 39,330 were works of fiction, 2758 histories, 2444 biographies, and 739 scientific works. With the American National Red Cross, the Library of Congress maintains a Braille transcribing service for the production of Braille manuscript. Lessons are arranged for, certificates of competency are granted, and manuscripts are prepared, bound, and distributed. During 1930-31, 247,708 pages of Braille were completed and, in book form, distributed among 53 institutions, libraries, and individuals. The students helped represented 34 colleges, high schools, and universities, and assistance was given to persons engaged in many callings. But great as is the service rendered, still more is required, and "no private gifts or public funds yet in sight can meet all the growing needs of touch readers."

#### Biochemical Research in India

THE Society of Biological Chemists in India, recently founded by the enterprise of certain members of the Department of Biochemistry of the Indian Institute of Science, Bangalore, has published a review of work carried out in India during 1930 ("Biochemical and Allied Research in India in 1930" Society of Biological Chemists, India). The Society was founded to co-ordinate the work carried out in various parts of the country, and to arrange for the holding of meetings either of members of the Society alone or in association with other societies, for the exchange of ideas and the reading of papers. At present it is not proposed to issue a journal, although this may be practicable in the future as the volume of biochemical research increases. The present review, a pamphlet of twenty pages, deals with work on enzymes and fermentation, agricultural, dairy, plant, animal, and pharmaceutical and medicinal chemistry, nutrition and bacteriology. Reference is made to nearly a hundred original papers published during the year, which incidentally was the first working year of the new Imperial Council of Agricultural Research. The important work carried out by Chopra and his collaborators at the School of Tropical Medicine and Hygiene in Calcutta on the chemistry of Indian drugs, and by McCarrison at the Pasteur Institute, Coonoor, on nutritional problems is referred to, and the hope is expressed that workers will soon be attracted to the field of chemical and biological assay of drugs. The review indicates the rich field for research awaiting the attention of biochemists and pharmacologists in India.

#### The Epithalassa of the Strait of Georgia

THESE conditions have been described by A. Hutchinson and C. C. Lucas (*Can. J. Research*, vol. 5, 1931, 231-284). The Strait of Georgia is a great basin connected with the sea by narrow passages which receive water from a number of large rivers, notably the Fraser River. The water from the latter is conserved during the summer and forms a marked upper layer, the epithalassa, which is characterised by low salinity and high temperature. The temperature may be as much as 10° C. above the water of the sea. Throughout the greater part of the region this epithalassa has a stability which is sufficient to

resist tidal and wave movement Abundance of fish food in the form of plankton is present, and the amount is greatest in the region where the most complete mixing of the river and the sea water takes place The data presented are thought to have an economic bearing upon the fisheries, the establishment of oyster beds, the development of clam beaches, of crab and shrimp industries, and in the location of summer resorts

#### Seismological Society of America

THE last two numbers of *Earthquake Notes* report the proceedings of the Eastern Section of the Seismological Society of America Arrangements have been made with the directors of the Society by which it is provided that longer articles read before the Eastern Section shall be published in the Society's *Bulletin*, the *Notes* being reserved primarily for notes and news The recent numbers contain a summary of the papers that were read at the annual meeting of the Section held at Columbia, S C, on June 11-12, 1931 Most of the papers are devoted to instruments and their records, with one recalling the Charleston earthquake of 1886, some of the effects of which were seen during an excursion to that city. We have also received the last four quarterly numbers (for July 1930-June 1931) of the valuable *Bibliography of Seismology* issued by the Eastern Section, in which the titles, with occasional brief abstracts, are given of four hundred memoirs dealing with earthquakes

#### Library of the Royal College of Surgeons

A LIST has been published of the volumes in the library of the Royal College of Surgeons ("List of the Transactions, Periodicals, and Memoirs in the Library of the Royal College of Surgeons of England" London: Taylor and Francis, 1931 2s 6d) This is the second edition, the first having been published in 1890 it contains about twice as many entries as the latter Perusal of the list shows that the library contains, in addition to the commoner periodicals devoted to medical and allied sciences, a great variety of pamphlets and journals of considerable historical interest, to which access is generally difficult The list should be of value to librarians and research workers who may desire to refer to papers published in the lesser known or ephemeral journals, as well as to those interested in the history of medicine.

#### Microlepidoptera of Eastbourne

IN vol 10 (second supplement) of the *Transactions of the Eastbourne Natural History, Photographic and Literary Society* for 1931, Mr Robert Adkin contributes a carefully prepared list of the 'Microlepidoptera' and the more primitive of the larger moths of the Eastbourne district The list is annotated with many natural history details of considerable interest, and is illustrated by twenty-five excellent photographic plates giving natural-size reproductions of many of the species enumerated The list is one which will commend itself to anyone interested in the groups of insects dealt with, and is obtainable at the Society's rooms at the Technical Institute, Eastbourne, price 3s. 6d net.

No 3256, Vol 129]

#### Retting of Wool

WRITING from the Wool Research Department, Massey Agricultural College, Palmerston North, New Zealand, Mr R. Waters says "It may be of interest to those engaged in wool research to know that the fibre may be broken down into its constituent cells by retting it in a culture of what appears to be a variety of *Bacillus vulgatus*, and that this process may conveniently be used to provide cell material for study The organism apparently does not attack the cells, the material obtained appearing quite normal" Details of the technique employed may be obtained from Mr Waters

#### Announcements

PROF E S GOODRICH, Linacre professor of zoology and comparative anatomy in the University of Oxford, has been selected by the Council of the Linnean Society of London as the recipient of the Linnean Medal, which will be presented to him at the anniversary meeting on May 24

It is announced in the *Fight against Disease*, the quarterly journal of the Research Defence Society, that the Hon Sir Arthur Stanley has accepted the chairmanship of the Society in succession to the late Lord Knutsford

It is announced in *Science* that Dr T W Stanton, geologist in charge of palæontology and stratigraphy in the United States Geological Survey, has been appointed chief geologist, succeeding Dr W C Mendenhall, who has become director of the Survey

MESSRS W and G Foyle, Ltd, 119 Charing Cross Road, W C 2, have just circulated a catalogue of medical books offered for sale by them, which many readers should find useful

A COPY of catalogue No 3, 1932, of Messrs Oppenheim and Co (Rare Books), Ltd, 317A Fulham Road, S W 10, has reached us It gives the titles of about 900 works dealing with science, and is particularly strong in sets and long runs of publications of the learned societies

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in education in the University of Manchester—The Registrar, The University, Manchester (April 2) A full-time engineering workshop instructor at the L C C Paddington Technical Institute—The Education Officer (T 1), County Hall, S E 1 (April 2) An assistant lecturer in pharmacy at the Bradford Technical College—The Principal, Technical College, Bradford (April 6) A professor of physics at University College, Southampton—The Registrar, University College, Southampton (April 16) A chief metallurgist for the Tata Iron and Steel Company, Jamshedpur, India—Tata, Ltd, Capel House, New Broad Street, E C 2 A head of the department of mechanical and structural engineering and building of the Borough Polytechnic, Borough Road—The Principal, Borough Polytechnic, Borough Road, S E 1.

### Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### Spectrographic Observations of Infra-Red Lines in the Auroral Spectrum

THE importance of obtaining auroral spectra in the infra-red has long been recognised, and such investigations have formed part of my spectroscopic programme for the new auroral observatory at Tromsø. Preparations were made last summer and through Dr Brucke and Dr Lacmann, of Berlin, I was recommended to use Agfa Infra-Red Plate 810 with a suitable

FIG 1

sensitiser. These plates were tested last autumn and found suitable. After having carried out some precision interferometer measurements of the wave-length of the auroral line 5577.35<sup>1</sup>, spectrographic exposures of the aurora with infra-red plates of the kind mentioned were begun under the guidance of Mr L Harang.

During an auroral display on Feb 4, two small glass spectrographs were in operation, each of them gave good spectrograms showing strong lines in the infra-red, and the well-known spectrum in the blue part. The strong green line is absent because the plate is very insensitive in that region.

The spectrogram (a) of Fig 1 gives the strongest lines, and was taken with a broad slit. As the neon comparison spectrum is somewhat overexposed, it is to be expected that this plate will give a less accurate wave-length determination than the spectrogram (b) taken with a narrow slit. Our wave-length deter-

minations will therefore be based on the latter spectrogram.

The spectrum in the infra-red has the appearance of one strong and one weak narrow band with sharp edges towards long wave-lengths. They have very much the appearance of band sequences belonging to the first positive group of nitrogen.

On account of the small dispersion in this region (1400 Å/mm on the original plate), wave-length determinations cannot claim any great accuracy. In order to estimate the possible error, we measured the strong lines 4208 and 3913, and we obtained the values 4207 and 3912 respectively. The average dispersion in this region is 122 Å/mm and the error of A. should correspond to 12 Å in the region of the infra-red auroral lines.

The wave-lengths found for these two infra-red auroral lines are  $\lambda = 7883$  strong,  $\lambda = 8095$  weak.

If the auroral line 5577 is to be identified with the oxygen line observed by McLennan, we should expect a number of oxygen lines to appear in the infra-red. The most prominent oxygen lines are the first principal triplet of the Runge-Paschen series (7772, 7774, 7775), the three triplets of the series of Kiess, one between 8233 and 8221, the second between 7952 and 7948, and the third between 7481 and 7476.

None of these oxygen-lines can be identified with the two infra-red auroral lines.

Nitrogen shows a spectrum in the infra-red very similar to that of the auroral spectrum (Fig 1 c), which belongs to the first positive group. For the wave-length of the strongest heads we find  $\lambda = 7722$ , and this cannot be identified with the strongest head of the auroral infra-red spectrum.

On account of the large intensity of the infra-red auroral lines, only oxygen and nitrogen can come into consideration. As they are not (O I) lines, they most likely must be referred to nitrogen. As the positive group appears fairly strongly in the auroral spectrum, it is to be expected on account of the mutual relation between the first and second positive group that the first positive group should also appear fairly strongly in the infra-red.

If we write the formula for the first positive group:

$$\nu = 10979 + 1718 4n_1 - 14 44n_1^2 - 1474 4n_2 + 13 98n_2^2,$$

then the strongest head in the infra-red auroral spectrum nearly coincides with lines of the first positive group corresponding to the following transitions

| $n_1$ | $n_2$ | $\lambda$ |
|-------|-------|-----------|
| 1     | 0     | 7885      |
| 7     | 7     | 7896      |
| 12    | 13    | 7863      |

The last transition can scarcely come into consideration.

In order to settle the question as to the exact interpretation of the infra-red auroral spectrum, we shall have to wait for more accurate determinations. Observations with a spectrograph of much larger dispersion are now in progress.

<sup>1</sup> NATURE, 129, 23, 1932

#### Origin of the Coronal Lines

THE spectrum of neutral oxygen has been analysed by Runge, Paschen, Hopfield, McLennan, and especially by Frerichs<sup>1</sup>. The deep terms  $^3P_{210} = 109837.3$ ,  $109679.2$ ,  $109610.5$ ,  $^1D_2 = 93970.3$ ,  $^1S_0 = 76045.6$  account for the green and red lines in aurora and nebulae ( $\lambda\lambda 5577$ ,  $6300$ ,  $6364$ ). Still, there are a few

isolated lines of groups in the spectrum unclassified and not connected by known terms. These groups are

- I (4)6654 121, (5)6374 292, (4)6366 282  
 II (1)6266 692, (2)6264 346, (5)6261 314, (1)6258 965, (3)6256 616  
 III (3)5995 198, (1)5993 102, (2)5991 852, (1)5991 255

Now the last group has been found to be a combination between the known term  $3p^3P_{21}$  (-3456 4, -3459 8) and a new term  $3D_{321}$  (-20135 2, -20141 1, -20142 8). This new term also combines with the ground triplet  $2p^3P_{210}$  and accounts for the unclassified lines, (0)770 70, (1)770 28, (2)679 39 in the far ultra-violet

The groups II and I can be connected by the term difference  $\Delta\nu = 19.8$  and interpreted as combinations between a new set of deep levels  $P = 94925.1$ ,  $Q = 94905.3$ ,  $R = 94898.7$ ,  $X = 79221.7$ ,  $Y = 78946.2$ ,  $Z = 78932.3$ . The line 6654 ( $Y^1D_2$ ) forms the link with the  $1D_2$  metastable level that involves the green and red lines in aurora and nebulae. The red coronal line 6374 29 is the  $XQ$  combination. Hopfield has already directed attention to the fact that this line may be interpreted as the unclassified oxygen line.<sup>2</sup> The newly detected red coronal lines,  $\lambda(2)6704$  (Grotrian 1929) and  $\lambda(8)6776$ ,<sup>3</sup> have the difference  $\Delta\nu = 158$ , that occurs in the  $2p^3P_{21}$  ground triplet of neutral oxygen, and form the combinations  $2p^3P_2 - 8P$  and  $2p^3P_1 - 8P$ .

It is now also possible to calculate from laboratory data the green coronal line 5303, known since 1869, but never identified, notwithstanding numerous attempts. All the strongest coronal lines in the visible spectrum are now connected with terms of neutral oxygen. The Zeeman effect of the line 6374 will possibly give us the nature of the new terms. It may be that the configuration  $sp^4$  plays a rôle

| CORONAL LINES |                           |                                |            |               |                                                                  |
|---------------|---------------------------|--------------------------------|------------|---------------|------------------------------------------------------------------|
| Int           | $\lambda$ obs<br>(Corona) | $\lambda$ calc<br>(Laboratory) | $\nu$ calc | Combination   | Author                                                           |
| 8             | 6775.90                   | 6775.90                        | 14754.1    | $2p^3P_1 - P$ | Mitchell, <i>Astr. J.</i> , 1, 1932                              |

| 12            | 6374.28                   | 6374.29                        | 15683.6    | $Q - X$       | Mitchell, 1932                                                   |
| 20            | 5302.78                   |                                |            |               | Campbell and Moore, <i>Lick Obs. Bull.</i> , x, 318, p. 13, 1918 |
|               | $5302.8 \pm 0.2$          | 5302.70                        | 18853.1    | $R - 2p^1S_0$ | Davidson and Stratton, <i>Mem. R. A. S.</i> , 64, 141, 1927      |
|               | $5302.6 - 5303.4$         |                                |            |               | Mitchell, 1932                                                   |

It should be noticed that the green auroral line 5577 and the green coronal line 5303 both have their origin in the same metastable level of the neutral oxygen level,  $1S_0$ . The mysterious 'coronium' turns out to be neutral oxygen.

In the near future we hope to publish a more extensive report on the spectrum of the solar corona.

### Passage of Neutrons through Matter

THE discovery by Dr J. Chadwick<sup>1</sup> of strong experimental evidence in favour of the existence of neutrons of mass approximately that of the proton makes it imperative that as many lines of attack as possible on the problem of determining the nature of this particle be developed. Thus, it is clearly very important to determine the nature of the field surrounding the particle. In order to investigate this, the simplest method is to examine the interaction of a neutron with other material particles such

as atomic electrons. Thus, the measurement of the number of ions produced per centimetre by neutrons of different velocity should lead to a method of determining the field. It has therefore been thought of interest to give a preliminary account of the results of theoretical calculations of the behaviour of possible neutrons in this respect.

As the mass of the neutron is nearly that of a hydrogen atom, it cannot be the one suggested by

FIG. 1

Pauli,<sup>2</sup> which has a smaller mass. The only models which seem at all likely for the particle are as below.

(a) A hydrogen atom in nearly zero quantum state. This possibility was discussed in 1920 by Lord Rutherford,<sup>3</sup> and experiments were actually carried out by Glasson<sup>4</sup> in the following year in order to ascertain if such particles occurred in discharge tubes. Recently, Langer and Rosen<sup>5</sup> have discussed this model from the point of view of quantum theory.

For such a system the interaction energy between an electron and a neutron would be of the form

$$e^2 e^{-\lambda r},$$

where the parameter  $\lambda$  would be connected with the energy of binding  $-E$  ergs, by some formula of the type

$$\lambda^2 = \frac{8\pi^2 m^* E}{\hbar^2}$$

The mass  $m^*$  would probably be nearly that of an electron, but, as the binding energy is almost certainly greater than the rest mass of the electron, it is somewhat doubtful what mass one should take.

(b) A dipole of strength  $a \sim 10^{-13}e$ . This model would seem to be less likely than the first.

Using the first and more probable model, the rate of loss of energy in collisions with electrons per centimetre path of a neutron in passing through a gas containing  $N$  electrons per c.c. has been calculated. It is found that this loss of energy is given by

$$-\frac{dT}{dx} = \frac{2\pi e^4}{mv^2} N \left\{ \log \frac{\lambda^2 + 4k^2}{\lambda^2} - \frac{4k^2}{\lambda^2 + 4k^2} \right\},$$

where  $m$  is the mass of the electron,  $\lambda$  is the field parameter defined above,  $v$  is the velocity of the neutron, and  $k = 2\pi Mv/\hbar$ ,  $M$  being the mass of the neutron. This formula is valid provided the velocity of the neutron is greater than the orbital velocity of the atomic electrons.

The interest of the above result lies in its difference from the corresponding formula for charged particles. Thus, for  $k < \frac{1}{2}\lambda$ , the above expression shows that the loss of energy decreases with decrease of velocity, a result very different from the case of, say,  $\alpha$ -particles. When  $k \approx \lambda$ , the variation with velocity is very slow,

and for  $k \gg \lambda$  the behaviour resembles that of a charge (this depends on the assumptions made regarding the internal field). This behaviour is illustrated in Fig 1

The peculiar form of the above expression lends itself readily to at least qualitative experimental test, and may help to determine the field of a neutron. The calculations are being extended to other models and to the consideration of nuclear collisions

### Radioactive Disintegration and Nuclear Spin

It is well known that in radioactive disintegration, an  $\alpha$ -particle escaping from the nucleus has to cross a potential barrier formed at great distances by Coulomb repulsion forces and at small distances by attractive forces of yet unknown nature. Wave mechanics permits us to calculate the transparency of such a barrier and to obtain the formula connecting the decay constant  $\lambda$ , the velocity  $v$  of the ejected  $\alpha$ -particle, the charge number  $Z$  of the disintegrating element, and the radius  $r_0$  of the internal nuclear region <sup>1</sup>

Using the experimental values of  $Z$ ,  $v$  and  $\lambda$ , it is possible to calculate the radii of different radioactive nuclei which are shown in Fig 1. For the thorium

FIG 1

and uranium families the values of the nuclear radii vary rather regularly with increasing atomic weight, whereas for the actinium family a number of irregularities is present. This may be either because the radii of this family really do vary irregularly, or because all the factors are not taken in account by the calculations.

In the formula by means of which the values of radii shown in Fig 1 have been calculated, the angular momentum  $l$  of an escaping  $\alpha$ -particle was supposed to be zero. The presence of angular momentum increases the height of the potential barrier (the centrifugal force added to the Coulomb forces) and gives smaller values of the decay constant for the given  $r_0$ , or, the other way round, the neglect of this momentum leads to too small values of the radius, which is just the case for some members of actinium family. On the other hand, if nuclear spins of different elements which have been investigated are examined, it is seen that the nuclei with even atomic weights (to which the thorium and uranium families belong) usually have no spin at all, whereas for those with odd atomic

weights (for example, the actinium family) the nuclear momenta can take rather different values (from  $\frac{1}{2}$  up to  $\frac{5}{2}$ ).

If the nuclei of the elements which are disintegrating and their products have different spins, the ejected  $\alpha$ -particles must have angular momentum. The formula for the decay constant can be, in this case, written in the form

$$\lambda_j = \frac{\pi \hbar}{2mr_0^2} e^{-\frac{4\pi e^2}{\hbar} \frac{(Z-2)}{v} + \frac{8e\sqrt{m}}{\hbar} \sqrt{(Z-2)} \sqrt{r_0(1-\sigma)}} \quad (1)$$

$$\sigma = \frac{\hbar^2 j(j+1)}{2m r_0^2} \frac{2(Z-2)e^2}{r_0} = 0.002j(j+1),$$

where  $\hbar$  denotes (Planck's constant)/ $2\pi$

Using this formula we can, for example, estimate the correct value of the atomic radius of actinium emanation by ascribing to the  $\alpha$ -particle escaping from this nucleus an angular momentum of about three units, which means that the difference between the nuclear spins of actinium emanation and actinium-A is about  $\frac{3}{2}$ .

Such calculations, although uncertain, can give some idea of the spins of radioactive nuclei. Considerations of the same kind can also be applied to the decay processes when escaping  $\alpha$ -particles leave the nucleus in an excited state, <sup>2</sup> although in these cases the estimations must be still more uncertain owing to the increase of the nuclear radius by excitation.

<sup>2</sup> G. Gamow, NATURE, Sept 13, 1930

### Molecular Structure of Polysaccharides

IN the issue of NATURE of March 5, Prof W. N. Haworth announces that he has isolated tetramethyl glucose by hydrolysis of a fully methylated cellulose, and, on the basis of this result, he makes certain suggestions regarding the probable dimensions of the cellulose chain. In addition, he states that he is undertaking a similar research on other polysaccharides, and the letter closes with a claim for reservation.

It ought not to be necessary to point out that this laboratory, in which the methylation process was developed and first applied to all types of carbohydrates, has been engaged continuously for more than twelve years on the general problem now included in Prof Haworth's reservation. The results reported by him, and others of a similar nature, have been known to us for a considerable time, but we have good grounds for the opinion that the interpretation of these results is beset with so many complications that early publication is inadvisable. At regular intervals during the past four or five years, however, the results have been communicated to the expert referees of the Carnegie Trust, which has, in part, financed the work.

In the circumstances which have emerged it appears to be desirable, in the interests of my collaborators, to synopsise, so far as this is expedient, some of the results already obtained by us.

**Cellulose**—When cellulose is methylated on a large scale and the product subjected to *graded hydrolysis*, only 2, 3, 6-trimethyl glucose is liberated in the first instance, the 2, 3, 4, 6-tetramethyl glucose being derived from the more resistant fraction of the methylated cellulose. It is still an open question if this result can be interpreted as a proof that cellulose possesses a long-chain structure, or if the amount of tetramethyl glucose formed can be used as the basis of calculating the length of the cellulose chain as a whole. This work has been conducted, with numerous variations, on cellulose derived from

five distinct sources and on material specially prepared in the Forest Products Research Laboratory

**Starch**—The corresponding results which we have obtained with starch vary according to several factors for example, the nature of the amylose used and whether the material is methylated directly or is subjected to a preliminary acetylation. When the hydrolysis of methylated amylose is carried out in stages, tetramethyl glucose can be detected in amounts varying from 3 to nearly 5 per cent, but of much greater importance is the observation that one fraction of the methylated amylose is convertible into a mixture of sugars, the composition of which varied within the following limits

|                               |                |
|-------------------------------|----------------|
| 2 3 4 6-Tetramethyl glucose   | 23-26 per cent |
| 2 3 6-Trimethyl glucose       | 55-52 per cent |
| 2 3- and 2 6-Dimethyl glucose | 21 per cent    |

This indicates that the group responsible for the formation of tetramethyl glucose forms part of a complicated fragment of the amylose complex, as otherwise no dimethyl glucose would be formed from a fully methylated derivative. We have shown that this dimethyl glucose is a mixture of 2 3- and 2 6-isomerides in approximately equal proportions when the amylose has been methylated directly, but this ratio is disturbed to 24 and 76 per cent respectively as the result of preliminary acetylation. This, in itself, indicates the extreme caution which must be exercised in applying the methylation method in conjunction with acetylation to polysaccharides.

**Inulin**—Trimethyl inulin when hydrolysed with oxalic acid yields, in addition to trimethyl  $\gamma$ -fructoses, a mixture of (a)  $\omega$ -methoxy-5-methylfurfural, (b) tetramethyl  $\gamma$ -fructose and (c) a trimethyl anhydrofructose. We find that the yields of tetramethyl  $\gamma$ -fructose have varied from 2.7 as a maximum to 1.7 per cent as a minimum, owing to partial conversion of the sugar into the furfural derivative. If all of the above products be calculated as tetramethyl fructose, inulin would consist of a chain of 25 fructose units, whilst taking the above yield of 2.7 per cent as a basis, the inulin molecule would contain 43 fructose units in the chain.

We have encountered so many complications in our studies of methylated polysaccharides (including the unexpected result that certain  $\gamma$ -fructose derivatives are readily transformed into derivatives of glucose) that we are reluctant to make far-reaching claims on the basis of having isolated such compounds as tetramethyl glucose and tetramethyl fructose under the conditions described, but this communication will serve to show the progress we have made recently in researches which were initiated in this laboratory and have not been discontinued.

### Vertical Tube Counter- and the Barometric-Effect of Cosmic Radiation at Sea-level

TURNING a long tube counter in a perpendicular plane, the number of recorded cosmic ray particles depends on the angle  $\alpha$  between the vertical direction and the axis of the tube. This vertical tube counter effect, first observed by Tuwim<sup>1</sup> at Potsdam, has now been measured more precisely and found to be in accordance with his theory of this phenomenon.

The number  $N_{\mu H}(\alpha^\circ)$  is proportional to  $\sin^2 \alpha$ , as shown in Fig 1. This straight line enables the elimination of experimental errors of the single measurements, and therefore the fraction  $N_{\mu H}(0^\circ)/N_{\mu H}(90^\circ)$  and the mean mass absorption coefficient of the cosmic

radiation can be found more exactly than before. In a lead screen, 10 cm thick, the coefficient was found to be  $(\mu/\rho)_{H_2O} = 8.01$  and  $8.12 \times 10^{-4} \text{ cm}^2 \text{ gm}^{-1}$  with the two tube counters No 21 and No 22 ( $r = 2.4$ ,  $l = 45.0 \text{ cm}$  and  $46.0 \text{ cm}$ ) respectively, in accordance with Tuwim's value  $(9 \pm 1) \times 10^{-4} \text{ cm}^2 \text{ gm}^{-1}$  obtained with tube counter No 15 ( $r = 2.4$ ,  $l = 15.3 \text{ cm}$ ).

Repeating the experiments in the open air at different barometric pressures, the straight line of the vertical tube counter effect is shifted parallel, showing thus the barometric effect<sup>2</sup> very clearly. Assuming a pure absorption phenomenon for this behaviour,<sup>3</sup> the mean absorption coefficient is  $(\mu/\rho)_{H_2O} = 1.67 \times 10^{-3} \text{ cm}^2 \text{ gm}^{-1}$ . From the vertical tube counter effect it was found to be  $(\mu/\rho)_{H_2O} = 1.69 \times 10^{-3} \text{ cm}^2 \text{ gm}^{-1}$  in the open air.

By two different methods, therefore, it is possible to measure accurately the absorption coefficient of cosmic

FIG 1

radiation with the same apparatus and at the same time, but without a special screen indispensable for the usual method of determining absorption coefficients.

The accordance of the two values for the open air confirms the theory of the vertical tube counter effect, and should be interpreted by this theory that the direction of the cosmic rays, acting in the counter, is not greatly different from the initial direction of the rays entering the atmosphere. The conflicting results of Skobeltzyn<sup>4</sup> with the Wilson chamber are therefore probably due to the greater statistical uncertainty of his measurements, for, according to him, no vertical tube counter effect of the cosmic radiation can exist.

### Molecular Refraction of Nitrobenzene

THE discontinuities observed by Mazur in certain physical properties of nitrobenzene in the neighbourhood of  $9.5^\circ \text{C}$ , and described in a series of communications to NATURE, call for further investigation. The sharp decrease in the dielectric constant<sup>1</sup> at  $9.6^\circ \text{C}$ , the distinct retardation in the heating curve<sup>2</sup> at  $9.5^\circ \text{C}$ , and the change in slope of the density-

temperature curve<sup>3</sup> at the same point suggest the existence of two forms of nitrobenzene

It seemed of interest to ascertain if any change in molecular refraction is observable in the neighbourhood of this temperature. Having a supply of B D H 'purified nitrobenzene' at my disposal, it was decided to carry out a few tests with it. It melted sharply at 5.3° C, a temperature 0.2° below that of Mazur's specimen. Its density (in air) was determined pycnometrically, with the following results

| t °C | Density | t °C | Density |
|------|---------|------|---------|
| 6.6  | 1.2168  | 15.4 | 1.2082  |
| 8.0  | 1.2159  | 24.4 | 1.1994  |
| 11.0 | 1.2127  | 26.1 | 1.1977  |
| 11.4 | 1.2122  | 29.6 | 1.1943  |
| 13.4 | 1.2101  |      |         |

The density  $d$  at any temperature can be calculated with considerable accuracy from the equation,  $d = 1.2233 - 0.00098t$ , for, when plotted against the temperature, a rectilinear curve is obtained. The results agree very closely with those of Tyrer<sup>4</sup> over his range of 13°-30° C, and also with the very recent data of Massy, Warren, and Wolfenden<sup>5</sup> over their range of 6°-14° C. These latter data had not been published when my experiments were carried out, in neither set of results is there any indication of discontinuity within the temperature ranges examined. The equation gives 1.2037 for the density at 20° C, which agrees closely with 1.2039 given in the International Critical Tables.

The refractive index was determined using sodium light, with a Pulfrich refractometer, the zero of which was checked against carbon disulphide and bromo-naphthalene. The results in the accompanying table were obtained

| Temperature °C | Refractive Index, $n$ | Molecular Refraction |
|----------------|-----------------------|----------------------|
| 6.4            | 1.55972               | 56.60                |
| 8.6            | 1.55893               | 56.62                |
| 9.2            | 1.55858               | 56.61                |
| 10.5           | 1.55786               | 56.60                |
| 13.5           | 1.55653               | 56.60                |
| 15.1           | 1.55565               | 56.59                |
| 20.6           | 1.55299               | 56.57                |

The value for  $n$  at 20.6° closely approaches the value 1.55291 for 20° given in the International Critical Tables (vol. 7).

The third column gives the molecular refraction calculated from Gladstone and Dale's formula,  $\frac{M(n-1)}{d}$ , where  $M$  is the molecular weight, taken as 123.07, and  $d$  the density as calculated with the aid of the equation given above.

The molecular refraction shows merely a minute and steady change with the temperature, amounting in all to approximately 0.1 per cent. These results, coupled with those of Massy and his co-workers, indicate that ordinarily 'pure' nitrobenzene exhibits no apparent discontinuities in such physical properties as have been examined in the neighbourhood of 9.5° C. To what cause, then, may the remarkable observations of Mazur be assigned?

### Hyperfine Structure of the Mercury Line 5471 Å

In an attempt to explain the observed complicated structure of the mercury arc lines, Venkatesachar and Sibaiya<sup>1,2</sup> first suggested nuclear moments of 1/2 and 3/2 for the various isotopes of mercury. More recently, Schuler and Keystone<sup>3</sup> in Germany and Murakawa<sup>4</sup> in Japan have explained the structure of some prominent mercury arc lines by ascribing a nuclear moment of 1/2 to the odd isotope with atomic weight 199 and 3/2 to that with 201.

Though the mercury arc lines have been analysed by a number of investigators, a re-examination of the lines has revealed in some cases the indubitable existence of satellites that have not been previously recorded. It is realised that one has to be very cautious before being certain of the existence of new satellites, often faint, in the case of lines that have been carefully examined by others. It is concluded, however, that even the line 5461 ( $6^3P_2 - 7^3S_1$ ) has undoubtedly one more satellite at  $-0.154 \pm 0.002$  Å. The structure was examined in a low density, long column mercury arc, using as the resolving apparatus fused quartz etalon plates (specially made by Messrs Adam Hilger, Ltd.) of 2 mm and 3 mm thickness, suitably silvered on both sides. The microphotometer record (kindly taken by Messrs Carl Zeiss) of the pattern obtained by using the 3 mm etalon reproduced in Fig. 1, shows clearly the position of the new satellite. Besides, the existence of a satellite in this region has been suspected by Lunell<sup>5</sup> so early as 1911, and later by Schrammen<sup>6</sup> in 1927. But so definite a satellite does not work into the Schuler-Keystone scheme even as a forbidden satellite.

Again, the line 5770 ( $6^1P_1 - 6^3D_2$ ) has shown a structure containing three additional satellites at  $-0.173$ ,  $-0.213$ , and  $-0.257 (\pm 0.003)$  Å. These new satellites for 5770 along with the complex structures of 4916 ( $6^1P_1 - 8^1S_0$ ) and 5026 ( $6^1P_1 - 7^3S_1$ ), recently given by Venkatesachar and Sibaiya,<sup>7</sup> indicate that the common level  $6^1P_1$  is more complicated than is assumed by Schuler and Keystone.

### Hibernation of Adders

THE hibernation of adders and the mechanism of the process are very little understood. To all intents and purposes there is an apparently complete suspension of vital activity, but from the biological point of view this cannot be, as the nutrition of the body tissue must go on. Recently while engaged in dissecting an adder, I preserved a portion of the lung tissue and had it sectioned in the usual way. Microscopic examination of several sections showed extensive deposits of adipose tissue immediately surrounding the tracheal ring. Similar islets of fatty substance were seen round the bronchi and bronchioles, and there was an extension of this type of tissue round the terminal

FIG 1—Adder lung showing adipose tissue round tracheal cartilage  
Photograph by N Morrison

alveoli and in the substance of the lung (see Fig 1). This appeared to me to be unusual, as one does not find adipose tissue in the lung of animals.

There is a possibility that for hibernative purposes Nature is capable of converting the interstitial tissues of the lung into adipose tissue. A good supply of fat ensures for the hibernating animal two things, namely

- (1) The possession of warmth for the organism
- (2) A reserve supply of energy when all other centres are exhausted

Fats are eminently suitable for the incalculably slow process of oxidation which goes on when respiration is almost suspended, during the process of hibernation. One can compare hibernation with a slow smouldering fire. It lasts as long as there is a combustible material. If that material is easily consumed, the fire will soon come to an end. If, on the other hand, the material is good fuel but burns slowly, the fire will keep going so long as Nature wants it. Fatty tissue serves Nature's purpose admirably in this direction, and my examination of the microscopic slides gave me the impression that the presence of so much fat in the pulmonary tissue was meant to give it the central control of hibernation. N MORRISON

### Behaviour in Invertebrates

A RECENT paper by Southern and Gardner<sup>1</sup> on the diurnal migrations of the Crustacea of the plankton in Lough Derg shows once more that observations by different workers on the behaviour of the same species of plankton animals are in many cases not in agreement. I have previously shown<sup>2</sup> that the copepod *Calanus finmarchicus* apparently behaves differently at one time of the year from another, this difference is, in a way, only *apparent*, as we are comparing individuals that are not strictly compar-

able, namely, *different broods* which have grown and developed under different conditions. If we compare the behaviour of similar broods from year to year, they appear to be the same. Is not this a side of the problem that has been rather overlooked in the past?

In comparing the behaviour of short-lived species from place to place, the comparison must be made between comparable broods that have developed under the same conditions. I have recently been able to show that there are possibly five distinct broods of *Sagitta elegans* during the year in the waters of the English Channel off Plymouth. Each of these broods is born and develops under different conditions brought about by seasonal changes. It is only natural to expect, therefore, that the individuals of each brood will have their own type of behaviour and seek optimum conditions that are different for those of other broods. ### Plato and the Modern Age

MR. W. G. LINN CASS, in his review of Mr. Lowes Dickinson's "After Two Thousand Years", remarks<sup>1</sup> that

"The extraordinary increase in scientific knowledge has vastly extended the realm of thought and revealed heights and depths which almost make the mind reel in contemplation of the physical universe"

And again

"turning to the thinker himself we find that he, for his part, has to spend so much time merely in the acquisition of knowledge, of which a certain minimum is essential, that he has little real leisure for serious meditation on the majestic but increasingly mysterious panorama of life which now unfolds before him"

These propositions seem to me to confuse the thinker with his telescope and even to suggest that it assembled its own parts. As a mere question of fact there is nothing 'reeling' in the mind of Sir James Jeans, for example, and no conspicuous lack of leisure for comparatively serious meditation in the many readers and listeners-in before whom he has displayed some of the mysteries of the universe. But is there not a deeper fallacy? Does the increase in scientific knowledge and the increasingly mysterious panorama of life really affect the mind of man in the sense indicated by Mr Linn Cass? If there were not this increase, the mind would decline in power. Its vigour is maintained at the same high level by the constant addition to the material of knowledge. The Hebrew star-gazer, who never held a telescope in his hand, wrote of 'the stars in their courses' with an astonishment not less than that of the astronomer of to-day. "We begin to see how insignificant our home in space really is", says the latter on page 117 of his book of that name, and the former said "When I consider . . . the stars, What is man, that thou art mindful of him?" Five billion years hence (if that is the correct figure) the new astronomer may be saying it again, and, haply, he will still refuse to be defeated by the contemplation of the physical universe, and will still contrive a foundation of faith on which to build his seat of knowledge among the stars. ## Research Items

**Inheritance of Mental Defect**—Mental deficiency, its causes and inheritance, has recently been discussed by Prof F A E Crew (*Eug Rev*, vol 23, No 4), who points out the well-known difficulty in defining accurately, from a biological, psychological, or even legal, point of view, the various types of mental aberration. Idiocy, imbecility, and mental deficiency are not a biological classification of types, nor are the grades of mental defect genetically classified by drawing the line of normality at a particular intelligence quotient. In many instances, hereditary transmission is operating, but there are different genetic types of mental defect. In certain cases, amentia appears to be a single recessive genic character. This type should show a higher incidence in cousin marriages. Other pedigrees show ordinary dominance of the inherited mental defect with a high incidence in the family. In other cases, the method of inheritance requires an explanation by sex-linkage or multiple recessive factors, or a dominant gene together with a dominant inhibitor. The nature of the defect will also differ in families, because any abnormality of the brain may result in a mentally deficient condition. References are also made to primary and secondary ('acquired') amentia and to the influence of the uterine environment and order of birth in amentia and Mongolism.

**Iroquoian Origins**—Dr W D Lighthall has communicated to the Royal Society of Canada (*Trans Roy Soc Canada*, series B, vol 25, sect 2) a study of the affinities of the culture of the Iroquois, in which he arrives at the conclusion that the Iroquois were intrusive in North America, reaching it from South America by way of the West Indies, and that ultimately the stock was of Melanesian origin. It is pointed out that the early situation of the southern Iroquois was largely within reach of the Atlantic by way of rivers, and precludes all theory of a south-western or Mound Builder origin. Their distribution points to a derivation from the West Indies, where Arawak and the later Carib culture presents affinities to the great Guarani stock of South America. Points in Carib culture to which attention is directed with regard to the Iroquois are the organisation of the people of Guiana into five closely allied tribes or nations each with its own council, the construction of their towns on rivers or lakes, absence of domestic animals and dependence on hunting, the use of arrow and blowpipe, type of canoe, the election and position of the chief, and descent in the female line. It is pointed out, further, that the Iroquois are of a tropical and islander character. In the use of a raised bed-platform, blow-gun and bow, the hammock, the double-headed maize pestle, the elaborate body-painting and tattooing, incised patterns on their pottery, and their long houses, they show resemblances to the Guarani. As regards Melanesia, attention is directed to the resemblances which Dr Rivet has found between Melanesian skulls and certain ancient American types, while Prof Dixon has pointed out the peculiar and primitive type of the long-headed Iroquois skulls. The tattooing and pottery ornament are held to be of Melanesian, and possibly ultimately of African, origin.

**Articulation of Joints in the Bat**—A photograph accompanying a note by Mr J H Vickers in the *Field* for Feb 20 (p 264) affords a correction and explanation of an error which is constantly repeated even in works of unexceptionable scientific authority—that the knee in bats is so rotated outwards by the

wing-membrane that it is directed backwards like the elbow. The illustration referred to represents a long-eared bat crawling in the upside-down position, with the left leg flexed at the knee and ankle in the same way as it would be by any other plantigrade mammal, although the foot is merely turned outwards and not forwards, the right leg is stretched out straight, with the toes pointing backwards and the knee upwards, which gives the elbow-like effect. The fact is that the freedom of action in the hip and ankle-joints in the bat is so great that the leg has more than the play of the human arm, and functions as an arm to such an extent that it is easy to see how the idea of the reversion of the knee-joint gained currency, especially as the bat can crawl in any direction, and is rarely seen on the flat in the quadrupedal position, though some illustrations show it thus, the pose of the hind limbs being merely an exaggeration of the straddle of the squirrel's.

**The Grass Embryo**—Dr Lucy Boyd (*Trans and Proc Bot Soc Edinburgh*, vol 30, part 4, pp 286-303) has raised again the controversial question of the homologies of the parts of the grass embryo, putting forward the view that the coleoptile is the first plumular leaf, whilst the epiblast is part of a vestigial ligule of the cotyledon, the opposite side of which is fused with the scutellum. Her views appear to have originated mainly from a consideration of evolutionary trends in Monocotyledons, the interpretations so suggested being supplemented by anatomical investigation. The series of types selected to illustrate the gradual reduction of the cotyledonary ligule to the final condition existent in the Gramineae is well chosen and suggestive. The evidence for the foliar nature of the coleoptile is less convincing. It is true that the derivation of the vascular supply to the coleoptile from the scutellum does not eliminate this interpretation, but, on the other hand, the same facts would apply if the coleoptile were regarded as part of the much modified cotyledon. Further facts are required before an agreement on this much-discussed question is likely to be general. It seems probable that a detailed comparison of the embryos from the earliest stages of development is most likely to give facts which may lead ultimately to a satisfactory interpretation.

**Permian of Texas**—The Permian System in Trans-Pecos Texas shows a more complete development than in any other part of North America, and is regarded by R E Evans (*Geology of the Glass Mountains*, Texas, part 2, *Univ Texas Bull*, 3042, 1930, pp 245, pls 44) as one of the standard sections of the Permian rocks of the world, comparable with the sections in the Salt Range of India, the island of Timor, and the Urals. In Texas the most complete Permian section is in the Glass Mountains, north of Marathon, where the system is represented by 7000 feet of strata divisible into six formations. A summary of the stratigraphy and palaeontology is given, but the main part of the work is devoted to a description of the brachiopods, of which 185 species and varieties, belonging to 47 genera, are recognised. These belong mainly to the Protremata and Telotre-mata, the Atremata are not represented, and only two forms of the Neotremata were found. The presence of the families Richthofenidae and Lyttonidae, and the abundance of the Productidae, are the most striking features in the brachiopod fauna.

**Pleistocene Climates of North China**—Prof G B Barbour has published a valuable paper on this

subject (*Bull. Geol. Soc. China*, vol. 10, pp. 71-104 (Grabau Anniversary Volume)). A brief description is given of fossiliferous continental deposits of late Pliocene and early Pleistocene age discovered near Taiku, Shansi. The contrast in character between the lower and upper members of the series points to a distinct change in conditions of weathering and throws new light on the climatic fluctuations. Three schemes of stage correlation with European stages are discussed, and the conclusion is reached that the facts are inexplicable without appeal to a shift of the earth's axis of rotation. The problems raised by each hypothesis are considered and directions suggested which may lead to a solution. Meanwhile it seems clear that the evidence is in close accord with Simpson's radiation control hypothesis, and that the warm climate inferred from the fossils and lithology of the Taiku beds supports the Wegener-Koppen hypothesis of polar shift. Dr. D. Black in a paper on "Palæogeography and Polar Shift" in the same journal (pp. 105-57) also adduces evidence favouring acceptance of the Simpson and Wegener-Koppen hypotheses. He writes: "The same set of hypothetical considerations as give adequate explanation of the extraordinarily varied Quaternary climatic conditions known to have obtained in North and South America, in Europe, Australia, Tasmania, and New Zealand, would seem in turn to yield equally satisfactory explanation for the peculiarly different climatic conditions characterising Asia during the same period." The paper is illustrated with twenty-six maps of the world representing the longitudes and latitudes corresponding to seven selected points on the assumed trajectory of the shifting pole.

**The Formation of Alto-cumulus Clouds.**—In a note on alto-cumulus cloud by C. S. Durst in the *Meteorological Magazine* for January 1932, new light appears to be thrown on the physical processes involved in the formation and maintenance of this type of cloud. Mr. Durst was led to consider the probable origin of the instability necessary for the formation of such convectional clouds with their bases at a great height above the earth's surface. It seemed to him probable that a combination of loss of heat by radiation from the tops of the clouds and gain of heat at their bases by radiation from the earth and the atmosphere below the clouds, might yield the simplest explanation. But there is the difficulty that alto-cumulus should according to this hypothesis be more frequent at night than by day, because of the considerable insolation usually taking place on the upper surface of the cloud during the day, which appears to be flatly contradicted by Russell's observations on the diurnal variation of frequency of these clouds in southern England. Durst has, however, found that Russell's figures, showing a marked minimum around 1 A.M. and 2 A.M., are greatly affected by the frequent difficulty of seeing alto-cumulus at night when it is present. When due allowance is made for this, it appears that the frequency at night is in all probability between two and four times as great as it is by day.

**Absorption of Hard  $\gamma$ -Radiation.**—Two exceedingly careful studies on the absorption of  $\gamma$ -rays are reported in the February number of the *Proceedings of the Royal Society*. One by C. Y. Chao is concerned with the variation with wave-length of the absorption in lead. It establishes that there are abrupt changes at about 6 X.U., the absorption passing through a minimum value, and the conclusion is drawn that this is connected with the existence of an excitation or disintegration potential for the lead nucleus. The other, by G. T. P. Tarrant, deals with the variation with atomic number of the absorption coefficient for

the monochromatic  $\gamma$ -rays from one of the members of the thorium family of elements. The curves expressing the results are more regular and comprehensive than those of earlier investigators, and agree with the best of these. For the light elements the absorption coefficients appear to be a little greater than would be expected from the theory of Klein and Nishina, but the origin of the discrepancy is not certain. For the heavy elements there is definitely extra absorption, and it seems now to be generally agreed that this represents in part a nuclear phenomenon, although the nature of this is not indicated so clearly by Tarrant's work as by Chao's.

**Cathode-ray Oscillographs.**—The importance of the cathode-ray tube as an instrument for measuring electrical quantities is a good example of the assistance that pure physics is constantly giving to electrical engineering. It also shows that unless the principles underlying the operation of the apparatus are clearly understood, erroneous conclusions may be drawn from its readings. At the Institution of Electrical Engineers on Feb. 5, two papers were read on these instruments. The first, by Dr. A. B. Wood, dealt briefly with some of the more important developments in their design and use. He considers that, of the various methods for focusing the cathode stream, the electrostatic method gives the best results. The recording of the effects of lightning is a difficult matter, owing to the uncertainty in the time of the arrival of the impulse. The timing in this case has to be automatic, the lightning impulse itself initiating the time deflexion of the cathode-ray spot. The second paper, by Prof. MacGregor-Morris and H. Wright, discusses possible sources of error in using these instruments for measuring purposes. Modern tubes have seldom serious faults due to defects in manufacture. The authors discuss the supposed 'threshold' effect. This effect, as generally stated, is that a definite value of the deflecting voltage has to be reached before any deflexion takes place. Their results show that this is only approximately true, as the sensitivity, although it is smaller, is not zero for small deflecting forces. For electromagnetic deflexions, no such effect was observed. Stress is laid on the necessity of calibrating the tube accurately. This should be done photographically, and should be carried out over the greater part of the surface of the fluorescent screen and not merely for two lines at right-angles to one another.

**The Determination of Nitrogen Peroxide.**—E. J. B. Willey and S. G. Foord have described a new and rapid method for the determination of nitrogen peroxide (*Proc. Roy. Soc.*, Feb.). White light from a constant source is filtered to give a narrow band of wave-lengths, then passed through an absorption tube holding the mixture to be analysed, and finally received on a photoelectric cell. From the current passed by the cell, which is measured by a Wynn-Williams valve bridge, the intensity of the light falling on the cell, and hence the amount of absorption by the peroxide, are determined, and from a preliminary calibration with known amounts of peroxide the amount of this present is then known. The device may be used for concentrations of  $1 \times 10^5$  and upwards. It has a number of interesting uses, including the regulation of temperature and pressure by a thermostatic control actuated by a variation in current through the cell caused by a shift in the equilibrium between the simple molecule ( $\text{NO}_2$ ), which is transparent, and the coloured polymer ( $\text{N}_2\text{O}_4$ ).

**Optical Activity in Diazo-Compounds.**—Although optically active diazo esters containing only one

possible asymmetric carbon atom bound to the diazo group have been prepared, their specific rotations are small, and compounds with large rotations previously obtained contain another asymmetric carbon atom and are very unstable. Suggestions have been made that the diazo esters have a ring structure. Ray (*J. Amer. Chem. Soc.*, Jan.) has now prepared a stable, optically active, crystalline aliphatic diazo-compound,  $\beta$ -naphthol-phenyldiazomethane, melting at  $120^\circ$  and having a high specific rotation, which shows that a carbon atom attached to the diazo group may retain its asymmetry. The compound was prepared from the active forms of the amine,  $\beta$ -naphthol-phenylaminomethane, by dissolving this in pyridine and, after addition of sodium nitrite, adding to cooled concentrated hydrochloric acid, when the diazo compound separated in light flaky lemon-yellow crystals. Its formula is decided by the fact that treatment with alkali does not racemise the compound, so that the diazo group and carbon atom are in a straight chain, the pentad nitrogen losing an electron to the carbon, to which it is otherwise united by an electron pair.

**Preservation of Railway Sleepers**—In *Forest Bulletin* No. 74 (Economic Series), 1931, Mr. F. J. Popham summarises the results of laying treated experimental sleepers in the various railway systems of India. The author states that it is now recognised that the open tank treatment given in the majority of the earlier tests is inadequate, and that treatment in a pressure plant, with the specification worked out

for each species, will give better results. Apart from one or two instances in which the iron pot sleeper was made use of, most of the premier Indian Railway main lines, when their first construction was undertaken during the 'sixties and 'seventies of last century, made use of either deodar, teak, or sal, the three chief timbers in common use in the country. The investigations into treated sleepers are concerned with other Indian timbers and the experiments here dealt with are confined to the five species *Pinus longifolia*, *Pinus excelsa*, *Dipterocarpus tuberculatus*, *Dipterocarpus alatus*, and *Terminalia tormentosa*. The preservatives used were carbolineum avenarius, zinc chloride and carbolineum avenarius, Powell's solution, and solignum and earth oil. So far the dipterocarps have been failures, whilst Powell's solution appears unsuitable in damp conditions, being subject to leaching. As was to be expected, certain anomalies have become apparent in the different tests, which further investigations will probably elucidate. An examination of the results in the Karachi division is of interest. The sleepers (the two pines and *Terminalia*) were Powellised and laid down in the main line in 1911. They were removed from the line in 1922, many of them suffering from rot. The best of these were selected and relaid in Palidan's goods yard in 1922 and have given excellent service since. In all probability they would have been removed from the main line by now owing to mechanical failure, but their life indicates their durability, so far as white ant and fungus attacks are concerned, when placed in a dry area.

### Astronomical Topics

**Conjunction of Venus and Mars in AD 864**—*NATURE* for Nov. 28, 1931, contained an article by Mr. J. H. Reynolds in which mention was made of an observation made by Habash at Baghdad of an extremely close conjunction of the above planets, the date is given by Mr. Reynolds as Oct. 10, but calculation by Dr. A. C. D. Crommelin shows that it should be Oct. 21 astronomically reckoned, or the morning of Oct. 22 civil. The calculation was made for Oct. 21 64 G.M.T., which is the time of sunrise at Baghdad, the accelerations adopted by Dr. Fotheringham and Herr Schoch were applied to Newcomb's tables, the centennial values are  $2.472''$ ,  $1.521''$ , and  $0.8087''$  for Venus, earth, and Mars respectively. The conjunction in longitude occurred about twelve minutes after sunrise, Mars being  $104''$  north of Venus. It would have been more than an hour after sunrise if the accelerations had not been applied, hence the phenomenon gives support to the accelerations. Mars was 2.22 units from the earth, hence it would be rather faint, and would probably not be visible later than twenty minutes before sunrise, at which time the distance between the planets would be about  $2'$ . The distance between the components of the 'double-double' epsilon Lyrae is  $3\frac{1}{2}''$ , and it needs an acute eye to divide it, it is doubtful whether any eye could separate Venus and Mars at a distance of  $2'$ , the calculation vindicates the accuracy of Habash's statement that they came so close as to appear one planet.

**The Orbit of 61 Cygni**—The *Observatory* for February contains a letter from Mr. A. Fletcher on the subject of the orbit that he has lately calculated for this star. The difficulty in this case is to determine the inclination of the orbit-plane to the line of sight, owing to the shortness of the arc covered by good observations, compared with the whole orbit. Since the parallax is very well known (Prof. Schlesinger adopts  $0.300'' \pm 0.003''$ ) and the absolute magnitudes

are thereby determined, Mr. Fletcher derives the masses from the mass-luminosity law, this gives the inclination, and the other elements follow. Their values are given in *Monthly Notices* of the Royal Astronomical Society for December as follows: Period 696.63 years, periastron passage 1686.37,  $a$   $24.525''$ ,  $e$   $0.40369$ ,  $i$   $+52.896^\circ$ ,  $\omega$   $153.917^\circ$ ,  $\Omega$   $172.823^\circ$ .

Peters' orbit, published in *Astr. Nach.* in 1887, gave the period as 783 years from a much shorter arc, so there is good reason for hoping that the new period may be in the neighbourhood of the truth.

**Report of the Naval Observatory, Washington, for 1931**—The six-inch transit circle was in use for observation of the sun, moon, planets, and fundamental stars, also for the Eros-comparison stars; Eros itself was observed 28 times on the meridian. A Shortt clock was received in November 1930, and was in use for most of 1931. Its rate was steady; there is a temperature variation of 0.07 sec. per day per degree centigrade, but as the temperature is kept very nearly constant, this is not important. A new clock vault will contain piers for seven clocks. With the 26-inch equatorial, Eros was observed 101 times, the satellites of Saturn on 28 nights. Sixty-five photographs of Eros were obtained with the 12-inch equatorial, using a yellow screen, as the objective is a visual one. Stars of magnitude 10 need an exposure of one minute; those of magnitude 14 need an hour. The sun was photographed on 303 days with the photoheliograph, spot activity continues to decrease, and the minimum is expected in 1933 or 1934.

In the Nautical Section it is noted that instruments have been constructed that give a continuous record of the direction of a ship's course as determined by the gyrocompass, with an accuracy of one-tenth of a degree, also instruments for giving a dead-reckoning position of the ship.

## International Atomic Weights\*

TWO changes in the table of atomic weights are recommended by the Committee on Atomic Weights of the International Union of Chemistry in its second report, which has just been published, the atomic weight of krypton is considered to be 83.7 instead of 82.9, and of xenon 131.3 instead of 130.2. The Committee, which consists of Prof G P Baxter (Cambridge, Mass.), Mme P Curie (Paris), Prof P Lebeau (Paris), and Prof R J Meyer (Berlin), reports on all the atomic weight investigations published during the period Feb–Oct 1931 which have come to its attention, future reports will cover a period of twelve months. Authors of papers bearing on the subject are requested to send copies to each of the five members of the Committee at the earliest possible moment.

Elements of which the atomic weight has been determined during the period under review by physico-chemical methods are nitrogen, carbon, sulphur, fluorine, krypton, and xenon, chemical methods have been applied to the study of nitrogen, silver, chlorine, and iodine, physical (mass-spectrograph) measurements have been applied to the calculation of values for lithium, caesium, boron, germanium, selenium, tellurium, tungsten, bromine, rhenium, ruthenium, and osmium, whilst a new determination of the relative proportions of the oxygen isotopes has been made by microphotometric evaluation of the band spectrum of oxygen.

Reference should first be made to the investigation last mentioned, because the results provide a new conversion factor for the calculation of 'chemical' atomic weights from 'physical' atomic weights, and emphasise the disparity between the two scales for the determination of atomic weights used respectively by chemists and by physicists. This "undesirable situation" arises from the fact that the chemical unit,  $O=16$ , takes no account of the existence of the three isotopes of oxygen,  $O^{16}$ ,  $O^{17}$ , and  $O^{18}$ , present, according to Mecke and Childs, in the ratio  $630 \pm 20 : 1 : 0.2$ . The physical unit is referred to the isotope  $O^{16}$ , and hence the two scales differ by one or two parts in ten thousand. The propriety of employing hydrogen, helium, or  $O^{16}$  as a chemical standard has therefore been canvassed, but in Dr F W Aston's opinion, communicated to the British Association last year, the present chemical standard amply satisfies all requirements of international atomic weights so far

as accuracy is concerned. The Committee agrees unanimously with Dr Aston, and therefore does not propose a departure from the existing unit. The new conversion factor is 1.00022, whilst the Naudé factor, at present in use, is 1.000125.

Nitrous oxide has been found by Batuecas to have a normal density of  $1.98042 \pm 0.00005$  (not 1.98038 as given in the original), this value being the mean of twenty determinations. Cooper and Maass report values of 44.0054 and 64.059 for the molecular weight of carbon dioxide and sulphur dioxide respectively, leading to atomic weights of 12.0054 for carbon and 32.059 for sulphur. Patterson, Whytlaw-Gray, and Cawood, repeating the work of Moles and Batuecas, find the molecular weight of methyl fluoride to be 34.046, and are of opinion that the true atomic weight of fluorine lies nearer to 19.010 than to 19.000 (see NATURE, 128, 375), despite Aston's view that fluorine is a simple element. By comparison of the densities of krypton and oxygen, Watson calculates the atomic weight of krypton to be 83.71, whilst Whytlaw-Gray, Patterson, and Cawood, by comparison of the pressures at which xenon and oxygen possess the same density, find the atomic weight of xenon to be  $131.26 \pm 0.005$ .

Gravimetric determination of the ratio  $Ag : NH_3$  by Baxter and Greene, combined with the ratio  $Ag : NO_3$ , gives, when chloride or dilute bromide solutions are used, the value 14.0078 for the atomic weight of nitrogen. Honigschmid corrects the results of silver chloride analyses by Honigschmid and Bedr Chan, and obtains a mean atomic weight for chlorine of 35.456<sub>3</sub> (gravimetric) or 35.456<sub>7</sub> (nephelometric). Thermal decomposition of iodine pentoxide, employed by Baxter and Butler, leads to the low value  $I=126.905$ , and the method is considered to be insufficiently precise. Combination of the ratios  $2Ag : I_2O_5$  and  $I_2 : I_2O_5$  affords the value 126.929. Determinations of the ratio  $AgI : AgCl$  by Honigschmid and Striebel give the low value 126.917 ( $Cl=35.457$ ). Aston's value, 126.932 ( $O^{16}=16$ ), corresponds with a chemical atomic weight of 126.918 or 126.905, according to the conversion factor employed, but is a mean of observed limiting values 126.907 and 126.957.

Calculation of atomic weights from mass spectra, using Naudé's equation, leads to the following results ( $O=16$ ): lithium 6.923, caesium 132.91, boron 10.806, germanium 72.65, selenium 78.96, tellurium 128.03, tungsten 183.96, bromine 79.916, rhenium 186.22, ruthenium, 101.1, osmium 190.31.

## Co-operation in Fisheries Investigations\*

THE twenty-fourth annual meeting of the International Council for the Exploration of the Sea was held in Copenhagen in March 1931. During the short interval of nine months between this meeting and the last, the general lines of work and instructions laid down by the Council have been followed. Three special conferences took place during the year, the first and second at Lowestoft, on the transplantation of plaice and on herring investigations, the third at Lisbon, on the sardine fisheries.

In reviewing the general work already accomplished, it is shown that striking progress has been

made in the 'technique' of prognostication of the fisheries. In the administrative report of the Committee of the Northern North Sea, the chairman is able to state with regard to the haddock that the work has reached the stage where the yield of the North Sea haddock fisheries for eighteen months or two years ahead can be anticipated with great accuracy. The report of the Southern North Sea Committee records, not for the first time, a successful forecast of the East Anglian herring fishery, and the report of the North and Western Area Committee records the complete justification of a forecast made in the previous year of the trend of the Icelandic cod fishery.

Extensive cod-marking experiments are being carried out by Denmark in Greenland and Iceland and show an interchange between cod populations

\* Report of British Delegates of the Meeting of the International Council for the Exploration of the Sea, held at Copenhagen, March 23–28, 1931. Drawn up by Henry G. Maurice and D'Arcy W. Thompson. Pp. 9. (London: Ministry of Agriculture, 1931.)

of Davis Straits and Iceland, the cod populations of Iceland being thought previously to be self-contained.

This year is the second International Polar Year, when polar hydrographical conditions will be specially investigated by all nations. It is hoped that intensive observations will be made of internal waves in the Southern Cattegat during a period of seven days in August. The English hydrographic programme includes an extension of the total current measurements which have been carried out at the Varne Lightship in the past.

The question as to whether the Limnological and the Plankton Committees should remain as separate entities was discussed, and it was decided to reconsider this at the next meeting.

Special scientific meetings on plankton and hydrology dealt with the conditions of plant life in the sea. Prof. Gran, as chairman of the Plankton Committee, reviewed recent work on the effects of phosphates and nitrates on the growth of plankton. From his own work he inclines to the belief that manganese and iron derived from coastal waters are necessary, in addition to phosphates and nitrates, for planktonic growth in Atlantic waters.

Dr Henry Bigelow, of Woods Hole Oceanographical Institution, attended the meeting as a visitor and outlined plans for future work in the North Atlantic in which the North American Council on Fisheries Investigations might co-operate with the International Council. The Council expressed appreciation of the work to be carried out on the western side of the Atlantic, and declared that the moment is opportune to enter into close co-operation with both the Woods Hole Institution and the North American Council of Fisheries Investigations, and that this can best be achieved by close personal touch between the workers. The Council invite representatives of both bodies to take part regularly in its deliberations, in order to arrive at unity of plan and methods in the study of those fundamental problems which are similar or identical on both sides of the Atlantic.

The conclusions of the delegates are that the organisation is on a thoroughly sound footing, that its reputation in the scientific world has grown and continues to grow, that the welfare of the fishing industry demands the continuance of scientific investigations, and that the Council should be encouraged to continue its useful work.

### Forestry in Trinidad and Tobago \*

THE keynote of the Annual Report of the Forest Department of Trinidad and Tobago (Trinidad, May 1931) is to be found in the opening paragraph on "Forest Resources." The conservator, Mr R. C. Marshall, is able to write "As a result of a considerable amount of detailed field work during the last few years, we are now in a position, in regard to a considerable area of forest, to be able to substitute a clear picture of the stand of timber for the vague general idea with which, in the past, we have had to be content." Unfortunately, in far too large a proportion of the Empire forest departments this vague general idea of the forest resources still persists. The survey of the forests in Trinidad is being effected by the well-known method of running lines in carefully considered directions 100 chains apart and enumerating the trees on the lines, thus obtaining a one per cent enumeration, 6000 chains of lines were run in 1929 and 5600 in 1930.

From the enumeration surveys already made, it is now established that the Colony's 600,000 acres of forest contain a very large amount of wood. This is supported by the stock-taking effected on 1000 acres of mora (*Dimorphandra mora*) in Mayaro, and on 1000 acres of mixed forest in the Central Range Reserve, in which crappo (*Carapa guianensis*) and guatecare (*Lecythus laevifolia*) form the most plentiful of the useful species. Appendix D gives the data of the species found on these two areas and is of great interest. It has established the fact that the mora forest in its constitution is far more comparable with the pure forests of temperate regions, which provide the bulk of the timber of commerce. It is considered possible, therefore, that this type of forest gives possibilities of regulated commercial working or 'lumbering' in the Colony. These two types of forest are representative of a large proportion of the forests of the Colony. "Increased utilisation of our forest resources", writes the Conservator, "hinges mostly on getting together stocks of timber and seasoning them properly." In view of the fact that the Colony imported £233,000 of forest produce during the year,

this rightly forms one of the problems which is receiving the closest consideration.

The two most popular woods in the Colony are said to be cedar (*Cedrus mexicana*) and balata (*Mimusops balata* var. *Cruegeri*). The enumeration surveys have shown the very small proportion which these species bear to the total crop, and that the younger age classes are very deficient. It is with satisfaction that we read that working plans are being prepared, and that in the case of cedar they prescribe and control the yield. Other plans are in course of preparation, one for the control of the mangrove swamps close to Port of Spain, which are a very important source of fuel wood for the city.

The Report is replete with details of progress which will have a far-reaching effect on the prosperity of the Colony. Mention can only be made of interesting silvicultural experiments and sowing and planting work, of investigations in connexion with forest soils in collaboration with Prof. Hardy, of the Soil Department of the Imperial College of Tropical Agriculture, and finally, in collaboration with the Trinidad Government Railway, a beginning has been made with wood preservation experiments in connexion with the treatment of mora sleepers. The administrators of the Colony are to be congratulated on the marked progress which their Forest Department has achieved in the past few years.

In Leaflet No. 4 of the Forest Department, Mr R. C. Marshall deals with the "Forest Trees of Trinidad and Tobago, with Special Reference to their Timbers". The leaflet gives a reasonably complete list of the more prominent forest trees, stating the size to which various species grow, their relative abundance, and giving in a concise form some information as to the timber they produce. It is not, nor does it purport to be, a complete list of all forest tree species. As noted above, there are 600,000 acres of forest in the Colony. With the exception of the mora forests, which are of special interest through the gregarious habit of mora and the large stocking per acre, practically all the remainder is of a very mixed type such as is common in tropical rain forest, to which category most of the forests belong. Two tabular statements are attached which show the trees by one foot girth

\* Trinidad and Tobago Forest Department Administration Report of the Conservator for the Year 1930. Pp. 22. (Trinidad Government Printing Office, Port of Spain, 1931.) 1s

classes, enumerated on 1000 acres of each type, these tables give some idea of the large number of species which constitute the mixed type of rain forest as compared with the mora forest

In Leaflet No 3 of the same Department a note has been drawn up by Mr R L Brooks, deputy conservator of forests, on "An Experiment on Air Seasoning of Native Timbers" Experiments with

some of the native woods have been carried out under the supervision of Mr Brooks, and so far as they have gone apparently justify the hopes of ultimate success The imports of lumber into the Colony are high, and Mr Brooks is definitely of opinion that they could be considerably reduced if stocks of seasoned local timber were made available

### Electrical Heresies

IN *Stanford University Publications*, University Series, Mathematics and Astronomy, vol 2, No 1, Fernando Sanford, emeritus professor of physics, discusses terrestrial electricity and related topics The volume, of 208 pages, is well produced and interestingly written; but it would form a very unsafe guide to knowledge The author propounds views that he recognises as being very heretical, and bound to meet with a hostile reception, but it would be mistaken to be disarmed by his candour in this respect His cardinal heresy is that "absolute electrical neutrality is unknown upon the earth, and could not be recognised if it were observed" (p 71)

Prof Sanford supposes that the ratio of the numbers of protons and electrons may be variable within wide limits upon different planets In particular, he believes that the sun and earth possess large negative charges—large enough, in the case of the earth, to explain the magnetic field as a result of the daily rotation of the charge He is aware of the familiar argument—simplest in the case of the sun—that the charge would be expelled by mutual repulsion and the outflow of electrons from the ionised solar atmosphere, but he denies that the electric charge upon a conductor exerts an outward pull upon the atoms of the conductor (though the experiment of an expanding charged soap-bubble would seem to indicate that they do), and that free electrons are held to the sun

by gravitation alone He asserts that electrons are apparently held to conductors by the pressure of the surrounding ether, which can sustain very great charges upon bodies His positive arguments for the existence of a large solar charge are based on the supposed necessity for considerable charge-densities to explain the magnetism of sunspots, and also of the sun as a whole, also upon the electron gas theory of the solar corona, and on the supposed electrical repulsion of comets' tails—all of them being highly debatable matters, certainly not yet explained according to the generally accepted laws, but very unsuitable as foundations for a striking break-away from these laws

Further, Prof Sanford suggests that electrical repulsions between the sun and planets may produce planetary perturbations (particularly for Mercury), and that the daily variation of the charge induced upon the earth by the sun can be detected His interpretation of his observations on this point is unlikely to gain favour, but the observations themselves might usefully be checked by other observers Later chapters of the book deal with the electrostatic field of the earth, earth-currents and magnetic variations, magnetic storms and solar activity, magnetic and electric influence of the moon, and barometric pressure and the earth's electric charge; to the reviewer they appear to abound with unlikely hypotheses

### International Congress of Prehistoric and Protohistoric Sciences

A PRELIMINARY outline of the arrangements for the First International Congress of Prehistoric and Protohistoric Sciences, which is to be held in London, has been issued, and it is announced that in order to meet the convenience of foreign delegates the date of meeting will be Aug 1-6, instead of July 25-30, originally arranged The first meeting will be held on the afternoon of Aug 1, and formal meetings will be continued during the week The following week will be devoted to excursions to places of archaeological interest The Congress will meet under the presidency of Sir Charles Peers, Mr R Holland-Martin will act as treasurer, and the general secretaries are Prof A W Brøgger and Prof J L Myres These appointments were made at the first meeting of the permanent council held in Paris in October last

In accordance with a further decision of the permanent council, the work of the Congress will be divided into sections, arranged according to practical requirements rather than on strictly scientific lines A classification of subject matter has been made for the first Congress, on the understanding that future division will be considered at the Congress The following is the list of sections, with the names of the British archaeologists who have been invited to act as presidents Human Palæontology, the Origin and Evolution of Prehistoric Man (Sir Arthur Smith Woodward), Palæolithic and Mesolithic Periods (Mr Reginald Smith), The Neolithic, Bronze, and Iron Ages in the Ancient World (Prof H J

Fleure, Prof J L Myres, Mr Sydney Smith), The Neolithic, Bronze, and Iron Ages outside the Ancient World (Dr H S Harrison and Prof C G Seligman), The Passage from Prehistory to History (Mr E T Leeds)

A number of questions has been placed on the agenda, although it is understood that communications on other matters may be offered, provided they come within the limits imposed by the statutes Among the subjects specifically mentioned are the present state of our knowledge of fossil man, discoveries of human industries in the drift and the loess, the mesolithic question, the megalithic monuments, the problems of the copper and early bronze ages in western Europe, the origin of Mediterranean civilisations, the oriental basis of Ægean chronology, Mediterranean contacts of the west European cultures of late bronze age and Hallstatt types, the Continental sources of racial and industrial types among the Anglo-Saxons, the origin and chronology of the Viking movements Communications must be sent to the Secretary of the British Organising Committee, Society of Antiquaries, Burlington House, Piccadilly, London, W 1, before May 1, 1932

Excursions have been arranged, to follow the Congress They begin on Aug 6, when those joining will be divided into two parties, of which one will stay at Oxford until Aug 9, visiting the Rollright Stones, Wayland's Smithy, Uffington, etc, as well as the Ashmolean and Pitt-Rivers Museums The second party will stay at Cambridge until Aug 9,

visiting Ipswich, Bramford, and Ely on one of the intervening days, and then proceeding to Oxford, where, after this party has inspected the Ashmolean and Pitt-Rivers Museums, the two parties will join to visit Salisbury and Devizes, returning to London on Aug 11. An extended excursion, to take in the west of England, and lasting from Aug 11 until Aug 15, will be arranged for those who desire, or as alternatives, arrangements will be made for a visit to Ireland, to include Tara, New Grange, and Monasterboice, or to Scotland, to include inspection of the Scottish National Museum and prehistoric sites in the neighbourhood of Edinburgh.

The subscription to the Congress is £1 for members and 10s for associates. Subscriptions should be sent to the treasurer of the Congress, at the Society of Antiquaries, Burlington House, Piccadilly, London, W.

### University and Educational Intelligence

CAMBRIDGE —The following grants have been made from the Worts Fund: £65 to L. S. B. Leakey (St John's College) for the continuation of archaeological and anthropological work in East Africa, £50 to A. Stephenson (St Catharine's College) towards the expense of publication of the results of the British Arctic Air Route Expedition, £30 to R. B. Roberts (Emmanuel College) and W. V. Lewis (Gonville and Caius College) for cartographical work in Iceland, £30 to R. M. Jackson (St John's College) towards the expenses of a geographical expedition to Spitsbergen, £25 to E. H. F. Baldwin (St John's College) for biochemical research at Tamaris, £25 each to P. W. Richards (Trinity College) and P. M. Synge (Corpus Christi College) for botanical research in Sarawak, £20 to S. R. Nockolds (Trinity College) for geological research at Carlingford.

The following have been elected to fellowships at King's College: Mr L. Barstow, scholar, who was placed in Class I Part I 1927 and in Class I Part II 1928 of the natural sciences tripos, as S. H. Ehrman fellow, Dr H. C. Darby, scholar of St Catharine's College, University lecturer in the faculty of geography, who was placed in Class I Part I 1926 and in Class I Part II 1928 of the geographical tripos.

EDINBURGH —The Senate has resolved to offer the honorary degree of LL.D. to the following, among others: Prof C. Vernon Boys, Mr David Middleton Greig, Royal College of Surgeons, Edinburgh, Dr R. Stewart MacDougall, formerly reader and Steven lecturer in agricultural and forest entomology in the University of Edinburgh, His Excellency Andrew Mellon, United States Ambassador, London, Prof Arthur Robinson, emeritus professor of anatomy in the University of Edinburgh, the Right Hon. Sir Archibald Sinclair, Secretary of State for Scotland, and Sir Josiah Stamp.

LEEDS —Prof J. W. Harvey, at present professor of philosophy in the University of Durham (Armstrong College), has been appointed professor of philosophy, in succession to Prof C. M. Gillespie, who retires at the end of the present session. Prof Harvey was educated at Bootham School, York, at Rugby, and at Balliol College, Oxford. He took a first class in classical honour moderations in 1909 and a first class in the final Lit. Hum., 1911. He was lecturer in philosophy in the University of Birmingham from 1912 until 1927, when he was elected to the chair of philosophy at Armstrong College.

LIVERPOOL —At the meeting of Council on March 13 it was agreed to confer the honorary degrees of M. Eng. and M. Sc., on July 2, on Mr H. H. Harrison and Mr

W. Horton respectively. Mr Harrison has published works on steam turbines, boiler feed injectors, and the historical basis of modern telegraph printing. Mr Horton has been honorary lecturer in plant histology in the University during the past ten years, and has distinguished himself by his investigations on the technical methods of histology and, in particular, by his work on the preparation of knife edges and the critical angles in the sectioning of waxes.

Prof Herbert E. Roaf, professor of physiology in the London Medical School, has accepted the George Holt chair of physiology in the University as from Oct 1, in succession to Prof J. S. Macdonald, who retires at the end of the present session. Prof Roaf was in succession Johnston colonial fellow, assistant lecturer in physiology, and lecturer in chemical physiology in the University of Liverpool. From 1911 until 1920 he was lecturer in physiology at St Mary's Hospital Medical School, London.

PROF A. H. STURTEVANT, professor of genetics at the California Institute of Technology, will lecture at the University of Birmingham during the autumn term of this year. He will be in residence at the University of Leeds on Jan 5–March 18, 1933, and afterwards proceed to Armstrong College, Newcastle. The lectures have been arranged in connexion with the scheme of the Carnegie Endowment for Industrial Peace, by which certain American professors will spend a year visiting universities in Great Britain.

THE directors of higher education from a number of different countries have just met, for the first time, at the International Institute of Intellectual Co-operation for the purpose of discussing various questions of great importance in the organisation and functioning of their university systems. The following were present: M. Jacques Cavalier (France), M. Ugo Frascarelli (Italy), Sir Frank Heath (British Empire), Prof Zoltan de Magyary (Hungary), Prof Werner Richter (Germany), and Dr Horatio Krams (American University Union in Europe, observer). The committee drew up a comprehensive programme for future work, envisaging, more particularly, agreements concerning university exchanges and the overcrowding of universities and of the liberal professions.

THE Ministry of Agriculture and Fisheries is offering five senior scholarships tenable at agricultural colleges or university departments of agriculture for diploma or degree courses in an agricultural subject, and 130 junior scholarships (including 10 extended junior awards for those who have already held junior scholarships) tenable at farm institutes for courses in agriculture, horticulture, dairying, or poultry husbandry. The awards are confined to sons or daughters of agricultural workers and *bona fide* workers in agriculture. Forms of application and other information may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W. 1, or from the offices of county councils. The latest date for receiving applications is April 30.

A LIMITED number of fellowships are being offered by the Salters' Institute of Industrial Chemistry to chemists of post-graduate standing. The object of the fellowships is to afford additional and special training preparatory to a career in industrial chemistry. The normal value of each fellowship is from £250 to £300. The Institute also offers a limited number of grants-in-aid to young men or women, not under seventeen years of age, employed in chemical works in or near London, who desire to extend their education for a career in chemical industry. Applications for the fellowships and grants-in-aid must be sent not later than May 1 to the Director, Salters' Institute, Salters' Hall, St Swithun's Lane, E.C. 4.

## Calendar of Geographical Exploration

March 28, 1907 — A Tragic Journey in Greenland

L. Mylius-Erichsen, with Capts Koch and Hagen, an educated Eskimo, Bronlund, and two others, left their winter quarters in Danmarkhaven, Greenland, lat  $75^{\circ} 43' N$ . The expedition had set out in June 1906, and the ship remained at Danmarkhaven for two years, while systematic observations were kept up at the base and the work of exploring to the north was carried on by sledge. Mylius-Erichsen and his party reached the eastern extremity of Greenland,  $81^{\circ} 29' N$ , charting the coast as they went. There they divided, Koch and two others reached Cape Bridgman in  $83^{\circ} 29' N$ , thus linking up with Peary's 1900 expedition, and returned safely. Erichsen, with Hagen and Bronlund, followed the coast westward into the deep inlet now known as Danmark Fjord. Keeping to the coast, they entered Independence Bay and pushed on to Cape Glacier in  $82^{\circ} N$ ,  $35^{\circ} W$ , on June 14, 1907. Here they were held by the softness of the snow all summer, and then time was lost on a drifting floe in an effort to cross Danmark Fjord. The only chance of escape was to travel southward over the inland ice and so cut off the eastern horn of Greenland, which the expedition had discovered. They succeeded in face of incredible difficulties in marching 160 miles in 20 days, but first Hagen and then Erichsen died, only Bronlund reaching the supplies left on Lambert Island on the northern journey. But Bronlund was worn out, and, after recording the journey in his diary, died alone in the Arctic night. His diary was discovered by Koch in the following year, and that of Mylius-Erichsen by Mikkelsen in 1910.

April 1, 1791 — Vancouver's Surveys

George Vancouver, with two ships, the *Discovery* and the *Chatham*, sailed from Falmouth. Vancouver had sailed as a midshipman under Cook on his last voyage, and he carried out his work of survey with remarkable thoroughness, being much helped by the fine quality of his officers. On Sept 26 the Australian coast was sighted and King George's Sound discovered. The northern coasts of New Zealand were surveyed to supplement the work of Cook, and the *Chatham* group was discovered. Vancouver then proceeded to the Strait of Juan de Fuca, which Meares had considered to be the portal to an inland sea occupying much of the continent of North America and thus making possible easy communication between the Pacific and Hudson Bay. Vancouver meticulously surveyed the labyrinth of channels, determined to leave unexplored no portion of the coast-line which might conceal a possible outlet to the Atlantic. He thus proved that no strait leading across to Hudson Bay could exist in these latitudes. The Columbia River was explored for 84 miles from its mouth. The *Discovery* arrived in the Thames on Oct 20, 1795, after her four and a half years' voyage, during which only one man of the crews of the two vessels died of disease. This arduous, prolonged, and detailed survey of the western coast of America is one of the most remarkable feats of exploration. It attracted little attention at the time, partly because it was scientific rather than spectacular in character, and partly because Vancouver sought no publicity.

April 2, 1906 — Archæology of Central Asia

Sir Aurel Stein started from Srinagar on the second of the three great journeys which have revealed so much of the ancient history of Central Asia. Though the main objects of these expeditions were archæo-

logical, Stein took with him trained surveyors who recorded topographical details with great accuracy. His 1906-8 expedition surveyed the region between Yarkand and the Nan Shan range, and extended his archæological work from Khotan and the Takla Makan (1900-1) to the Lob Nor region and eastwards to China. The third journey covered the whole region between the Tian Shan on the north and the Kuen Lun on the south, extending from the Pamirs to China. Stein has supplemented his classic memoirs on the early history of Chinese Turkestan and Kansu by a series of maps and a geographical memoir.

ERRATUM — Under date "March 14, 1864", for "Sir S. W. Butler" read "Sir Samuel Baker".

## Societies and Academies

LONDON

Geological Society, Jan 27 — G. M. Stockley. The geology of the Ruhuhu coalfields, Tanganyika Territory, with a report on some fossil plants from the Karroo beds in the Ruhuhu River depression, by J. Walton. The area, which is occupied by Karroo rocks, forms a depression between the mountains which lie to the north and south, these are composed of gneisses and other rocks of the primitive system, which are brought into juxtaposition with the Karroo rocks by faults of considerable magnitude. The rocks of the primitive system fall into three groups: (a) highly altered felsitic and acid volcanic rocks, (b) metamorphosed sedimentary rocks, consisting of quartzites, marbles, opicalcites, phyllites, and mica-schists, (c) gneisses and granulites. — L. R. Cox. *Lamellibranchia* from the Karroo Beds of the Ruhuhu coalfields, Tanganyika Territory. Five species, all referable to the genus *Palaeomutela* Amalitsky, are recorded from the lower horizon. Amalitsky's conclusion that the Lower Beaufort mollusca are in most cases identical with species found in the Permian of the Oka-Volga basin and other districts of Russia receives support from the material now studied, although it is considered that the fourteen species recognised by him in his South African material (which has been re-examined) should be reduced to five or six. The upper horizon has yielded numerous shells belonging to a new species of the genus *Unio*, *Unio* has previously been recorded from about the same horizon in North America (several species) and the Dolomites (one species), but not from older rocks. — S. H. Haughton. On a collection of Karroo vertebrates from Tanganyika Territory. The fauna of the Lower Bone Bed, containing Pareiasuria, Dicynodontia, Endiothodontia, and Gorgonopsia, and including new genera and species, is closely allied to that of the Lower Beaufort beds of South Africa, and the horizon is considered homotaxial with the middle part of the Lower Beaufort beds and the equivalent of the upper bone horizon of the Chiweta beds of Nyasaland (Upper Permian). The Upper Bone Bed displays a mingling of Anomodontia with Diapsida (Thecodontia and Theropoda). The Thecodontia are distinct from any known form, but the fauna as a whole shows certain similarities to that of the Rio do Rasto beds of Brazil and the Maleri Stage of India. The conclusion is reached that the beds are probably homotaxial with the non-reptile-bearing Molteno Beds of South Africa (Upper Triassic).

Institute of Metals, March 10 — G. D. Bengough and L. Whitby. Magnesium alloy protection by selenium and other coating processes. These films confer considerable resistance to the corrosive action of sea-

water spray. They are normally produced by immersion for a few minutes in a bath containing selenious acid at laboratory temperature, but may also be produced by rubbing the alloy with porous material dipped in the bath. The film has the property of self-healing to a limited extent, especially when immersed in stagnant sea-water, it is only a few thousandths of a millimetre thick.—Marie L. V. Gayler and G. D. Preston. The age-hardening of some aluminium alloys of high purity. Age-hardening of a duralumin at room temperature and at  $200^{\circ}\text{C}$  is due to some process, as yet undefined, which takes place prior to actual precipitation of  $\text{CuAl}_2$  or  $\text{Mg}_2\text{Si}$  from the aluminium lattice. In conjunction with existing equilibrium data, it is suggested that  $\text{Mg}_2\text{Si}$  as well as  $\text{CuAl}_2$  plays an important part in the process of age-hardening.—C. F. Elam. Some bronze specimens from the royal graves at Ur. Some of the objects found by Mr. C. Leonard Woolley had been cast, others showed signs of subsequent working and annealing.—W. H. J. Vernon. The 'fogging' of nickel. The effect is attributed mainly to the catalytic oxidation of small amounts of atmospheric sulphur dioxide, suspended sulphates play a minor part. There is a critical relative humidity, below which the metal may be exposed, apparently indefinitely, without action taking place, and above which fogging readily occurs. Film formation is approximately halved when light is completely excluded. The formation of the primary film may be largely suppressed by pre-exposure of the metal to an atmosphere containing traces of hydrogen sulphide. Fogging may also be inhibited by alloying the nickel with chromium, or by covering the surface with a film of lanoline.—H. J. Gough and H. L. Cox. The behaviour of single crystals of bismuth subjected to alternating torsional stresses. Throughout the tests no slip bands were observed. In the early stages of the tests numerous bands were produced parallel to the twinning planes, and finally cleavage cracking occurred. The production of twin bands appeared to depend on the sheer stresses on the twinning plane. On the basis of minimum energy, there is no reason to associate any type of movement with stresses tending to cause this movement by the shortest geometrical path, and the process of twinning may be due to stresses which at first sight appear to be incapable of affecting the process.—P. Saldau and M. Zamatorin. The solubility of aluminium in magnesium in the solid state at different temperatures. The solubility of aluminium in magnesium of 99.68 per cent purity has been determined at temperatures up to  $420^{\circ}\text{C}$ . The solubility limit at room temperature is 6.08 per cent aluminium by weight, and this is maintained unchanged until  $300^{\circ}\text{C}$ , after which a rapid increase occurs, the solubility line passing through 10.9 per cent by weight of aluminium at  $400^{\circ}\text{C}$ , and intersecting the eutectic line ( $436^{\circ}\text{C}$ ) at the point corresponding with 12.6 per cent aluminium by weight.—H. O'Neill and H. Greenwood. Observations on the pressure of fluidity of annealed metals. The pressure of fluidity at room temperatures has been designated as the stress at which a loaded rigid punch continuously penetrates a block of ductile metal. Examination of such a partly-punched specimen by hardness tests after sectioning, reveals that the most highly strained regions have a (Meyer) ball index value of  $n=2.0$  and a resistance to indentation equal to the pressure of fluidity. The value of the latter for a given specimen can therefore be determined by a cone or ball test after cold-working the material to the greatest possible extent by rolling. The suggestion is made that the condition of 'critical plasticity' observed by Tresca, Kick, Coe, and others in the course of compression tests, corresponds with the condition

of 'necking' in tensile tests.—W. Rosenhain. The testing of castings. Ideal methods of non-destructive testing being as yet unavailable, the application of the usual mechanical tests to castings is considered. The author favours the adoption of a separately cast test-piece, the use of small samples cut from actual castings being reserved for investigatory purposes. The use of chill-cast and sand-cast test-bars is discussed with special reference to the forthcoming adoption of a standardised sand-cast test-bar for the light alloys of aluminium. Reference is also made to the difficulty of determining small percentage elongations, and the practice followed in cast iron testing of using bending tests, in which deflection is measured as a means of testing ductility, is described.

#### PARIS

Academy of Sciences, Feb. 8.—L. Lecornu and Charles Richet. The rheometric disc, a simple apparatus for measuring the velocity of (ocean) currents.—L. Cayeux. The magnesium deposits of the Paris basin, regarded in their relations with breaks of equilibrium of the sea floor.—William Bowie. A possible cause of earthquakes not evident at the surface of the globe.—Maurice Gignoux was elected *Correspondant* for the Section of Mineralogy.—Paul Delens. The spherical representation of congruences.—Paul Mentre. The projective application of the tetrahedral harmonic complex on the non-special linear complex.—J. Delsarte. A matrix equation.—Jacques Devisme. Some partial differential equations.—Mandelbrojt. The rôle of the Borel monogenic functions in the theory of the Dirichlet's series.—Davin. The elastic and plastic state of an indefinite body in two dimensions perforated by a circular hole and under the action of a uniform force at infinity.—Enrico Volterra. The propagation from ram strokes through a node of a network of mains.—Thadée Banachiewicz. The determination of the vectorial constants of the orbit from two heliocentric points of a star.—Benjamin Jekhowsky. The angle  $S$  which determines the orientation  $j$  of the grand circle of asteroids.—Ch. Volet. The calculation of parabolic double stars.—D. Wolkowitsch. Applications of the ellipsoid of inertia.—E. G. Barrillon. The congruence of straight lines of thrust.—N. Gunther. The problem of cooling.—Pierre Vernotte. The propagation of a velocity of heating in a metallic bar.—M. Pauthener and Mme. M. Moreau-Hanot. The experimental control of the movement of small metallic spheres in an ionised electrical field.—G. Nadjakoff. The formulæ of the three classes of torsion electrometers.—P. Geoffroy and T. Koulomzine. Contribution to the geological study of the massifs known as primary of the Middle Chelif (Algeria).—Paul Fallot. The accidents of the Rif chain along the Xauen transversal.—Henri Erhardt. The nature and the genesis of the palæo-soils of the old loess of Alsace.—Gandillon. Project for utilising the Lake Maracaibo region in Venezuela. It is proposed to divert two small streams now flowing into the lake into the sea, close the neck with a narrow barrage, and after lowering the level of the lake by evaporation, to develop water power by allowing the sea to flow in.—N. Arabu. An attempt at a new classification of the ammonoids of the Trias.—Joseph Lefèvre. A case of unilateral heredity presented by wheat.—P. Vignon. The posterior wing of the Coleoptera.—Mme. L. Randon and Mlle. A. Michaux. The variations, during acute experimental scurvy, of the quantities of sodium and potassium eliminated by the kidneys and present in the blood serum and total blood.—Paul Portier and Frank Emmanuel. The absorption of heat radiations by the wings of Lepidoptera.—Paul Durand. The Weil-Félix reaction in

eruptive fever—D Santenise The hormonal individuality of vagotonin The author compares the properties, chemical and physiological, of vagotonin, a hormone which can be isolated from the pancreas, and insulin, and concludes that insulin and vagotonin are distinct Both hormones are secreted by the liver —M Loeper and A Mougeot The lipo-selection of cations, a new method in experimental hydrology.

## ROME

Royal National Academy of the Lincei Communications received during the vacation, 1931 —S Pincherle A special linear operator (2)—E Pinte Developes of curves in Hilbertian space —L Fantappiè The general expression of linear analytic functionals —M Ghermanesco. The  $n$ -metaharmonic functions of  $p$  variables —B de Finetti The characteristic functions of instantaneous laws endowed with exceptional values —G Lampariello Elastic waves in anisotropic media —G Krall Adiabatic influences of the tides in the Keplerian motion of two gyroscopic celestial bodies —A Weinstein The movement of a fluid through a permeable barrage —A Rosenblatt The stability of the laminar movements of viscous liquids (3) Convergence of the algorithm —G Righini The profile of the line  $\lambda 5183$  of magnesium in the solar spectrum The author's earlier determinations are upheld against the criticisms of Plaskett —V Ricca The Raman spectrum of sulphuric acid and the action on it of an electric field The phenomena arising from the action of an electric field on the Raman spectrum of sulphuric acid are explainable by supposing that the effects on the non-modified lines of the spectrum are due to the motion of the hydrogen ions in the direction of the field, and those on the Raman lines partly to the same cause and partly to the orienting action of the field on the ions —Leo Pincherle: Hull's magnetron A method is given for the theoretical determination of the wave-length of the high-frequency oscillations (electronic oscillations) emitted by Hull's magnetron in the case when the magnetic field is parallel to the axis of the diode —V Polara The Raman spectrum in sugar solutions The Raman spectrum of saccharose exhibits five of the seven lines of the glycerol spectrum and four lines of alcohol spectra It displays, moreover, the various types of linking which, in the molecular structure of compounds of the aliphatic series, are considered to correspond with particular Raman lines —G Scagliarini and P Pratesi Volumetric determination of vanadium and molybdenum Electrochemical considerations on the reducing activity of metallic copper It was shown previously that, in presence of sulphuric acid, copper quantitatively reduces  $\text{Fe}^{\text{III}}$  to  $\text{Fe}^{\text{II}}$  and  $\text{U}^{\text{VI}}$  to  $\text{U}^{\text{IV}}$ , but is without action on  $\text{Ti}^{\text{IV}}$  and  $\text{Cr}^{\text{III}}$  It is now found that, under similar conditions, vanadium and molybdenum undergo quantitative reduction in accordance with the schemes  $\text{V}^{\text{V}} + \text{Cu} = \text{V}^{\text{III}} + \text{Cu}^{\text{II}}$  and  $2\text{Mo}^{\text{VI}} + \text{Cu} = 2\text{Mo}^{\text{V}} + \text{Cu}^{\text{II}}$  —V Caglioti and P Agostini The use of X-rays in quantitative analysis —V Famiani Contribution to the knowledge of the nutritive values of certain cereals Tallarico has shown recently that small-corned grain has a greater nutritional value for turkeys than grain with large corns This result is now confirmed by the data yielded by experiments on growing albino rats fed with wheat, maize, or barley —Giambattista Dal Piaz Course of the lines of dislocation accompanying the intrusive masses of Mounts Croce, Ivigna, and Bressanone in the Upper Adige Tectonic peculiarities of this region indicate that the vast intrusive arch of the Croce-Ivigna-Bressanone-Pusteria mountain range, the tertiary

and non-Palaeozoic age of which has been confirmed by recent investigations, is included in the Dinaric series —G Mezzadrol and E Vareton Comparison between the actions exerted on the development of silkworms by a simple, open oscillating circuit and by one in syntony with a radio-oscillator for ultra-short waves In comparison with the effect of a simple, open metallic circuit, that of an oscillating circuit syntonised with a radio-oscillator results in more rapid development of silkworms, which grow larger and more resistant to disease, form cocoons sooner, and give a greater yield of cocoons

## WASHINGTON, D C

National Academy of Sciences (*Proc*, 17, Nov 15) —George H Parker and Virginia L Paine Progressive degeneration of the lateral-line nerve in the catfish The nerves of several fish were cut behind the gills and the fish killed at regular intervals Secondary degeneration in the myelin sheath moves peripherally and slowly over the nerve The degenerative wave seems to be a progressive metabolic change due possibly to the cessation of supply of a substance from the nucleated region of the neurone —T W Torrey The relation of taste-buds to their nerve-fibres Taste-buds on the barbels of the catfish disappear within eleven days of cutting their nerve supply Degeneration takes only one day Lowering the temperature postpones onset of degeneration but does not affect the time required for degeneration A chemical material is suggested as necessary for the maintenance of taste-buds and for the maintenance of the nerve itself —G H Parker (1) The colour changes in the sea-urchin *Arbacia pustulosa* was reported by Uexkull to be brown in darkness and deep black in the light No colour change has been detected in the allied form *A punctulata* The general conclusion is that chromatophores with their associated colour changes occur in the animal kingdom only when eyes and central nervous organs are sufficiently developed to enable an organism to respond to a luminous environment —(2) Effects of acetyl choline on chromatophores Has slight effect on a common killifish, but none on a spotted frog —Wilder D Bancroft and John E Rutzler, jr Reversible coagulation in living tissue (8) Bulbocapnine is an agglomerating agent for protein sols both *in vitro* and *in vivo* —Karl Sax Crossing-over and mutation Work on *Drosophila* shows a high correlation between crossing-over and mutation, maximum frequency of both occurring at the same region in the chromosome It is suggested that mutations are produced by crossing-over, the most probable agency being unequal crossing-over, natural selection tends to eliminate unequal crossing-over, and this decreases rate of mutation —H. Beckett Lang and John A Paterson A preliminary report on functional psychoses A report of cases of dementia praecox, manic depressive and epileptic psychoses treated on the lines of suggestions made by Prof Bancroft and his collaborators that these conditions are due to over-peptisation or agglomeration of nerve colloids The general conclusions from the effects of treatment with sodium amytal and sodium rhodanate are that these psychoses are accompanied by changes in the nerve colloids, and that these drugs afford a method of observing the effects of known methods of treatment —William T. Richards The heating of liquids by the absorption of sound, and its relation to the energy of intense high-frequency sound waves Dielectric loss in the liquid due to the oscillating electric field producing the sound waves, and contact with the oil transmitting the sound waves and with the containing vessel, are important sources of heat. An apparatus designed to avoid these difficulties gave

for 25 c.c. of water a heating effect of about  $2.5^{\circ}\text{C}$  per minute, corresponding to  $28\text{ cal min}^{-1}\text{ cm}^{-2}$  for an input of 2.5 kw. Bigger effects quoted by other investigators are due mainly to dielectric loss and oil heating—W. H. Zachariassen. The crystal lattice of calcium metaborate,  $\text{CaB}_2\text{O}_4$ . The oscillating crystal method was used. A feature of the structure is the endless strings of  $\text{BO}_3$  groups parallel to the  $c$ -axis—Roy J. Kennedy and Edward M. Thorndike. A search for an electrostatic analogue to the gravitational red shift. An electrodeless discharge in mercury vapour, which could be submitted to an electrostatic field, was examined at zero potential and at potentials of about 50,000 volts above or below zero, by a quartz interferometer maintained at zero potential. No significant change of frequency was observed.

## Forthcoming Events

TUESDAY, MARCH 29

ITALIAN SOCIETY OF EXPERIMENTAL BIOLOGY (Annual Meeting) (at Institute of Physiology, Turin University) —Subjects for discussion—The Carbonic Anhydride Equilibrium in the Blood, introduced by Prof. R. Margaria, and Pharmacological Action and Radioactivity, introduced by A. Benedicenti.

WEDNESDAY, MARCH 30

ITALIAN SOCIETY OF EXPERIMENTAL BIOLOGY (Annual Meeting) (at Institute of Physiology, Turin University) —continued

THURSDAY, MARCH 31

ROYAL AERONAUTICAL SOCIETY (Annual General Meeting), at 6.30

FRIDAY, APRIL 1

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual General Meeting) (at Engineers' Club, Manchester), at 7.—F. J. Slee. Laboratory Tests of Lubricants and their Relation to Engine Tests.

## Problems of Science Teaching

TWO striking addresses dealing, *inter alia*, with the teaching of science in secondary schools have recently appeared—the Pedler lecture of the British Science Guild, by Prof Irvine Masson,<sup>1</sup> and the presidential address to the Science Masters' Association, by the headmaster of Harrow.<sup>2</sup> They go back once more to the views of Huxley, to those of the representative committees of the British Association of 1917 and 1928, under the chairmanship of Sir Richard Gregory,<sup>3</sup> and to those of the Prime Minister's Committee of 1916–18 presided over by Sir J J Thomson,<sup>4</sup> when they suggest that for the vast majority of boys (and girls) what is needed is an all-round training in science, broad and simple, and including not only physics and chemistry, but also biology, geology, and astronomy.

The change would involve sacrifices both on the literary side and, for pupils who already take science, on the scientific side. On the scientific side, Prof Masson suggests that the prematurely intensive study of a particular science at school is directly harmful to the later study of the science itself. This proposal, however, raises other problems, and some of fundamental importance not obvious at once, both in education, in its narrower sense, and also in citizenship. Like Dr Norwood, we hear the contemptuous 'Smattering!' of some of our readers, nor are we unmindful of 'H E A.'s' courageous and reiterated demand that what should be taught in secondary schools is 'scientific method',<sup>5</sup> and his plea that in the right kind of scientific teaching the principle must be insisted on that 'nothing may be taken for granted'.

The doctrine is a simple one—unfortunately, too simple for truth. Even the author of the epoch-making "Discours de la méthode", Descartes, did not suspect all the things he took for granted, and the 'deductions' cheerfully made by a schoolboy from the simplest scientific experiment may be matters still under discussion by the keenest scientific intellects of our time. Imagine a teacher working through the more important books on method published since Mach's "Science of Mechanics"—we have in mind authors like Karl Pearson, Poincaré, James Ward, Russell, White-

head, T P Nunn, N R Campbell, Meyerson, H Levy, and the quite recent books by Dr Herbert Dingle on "Science and Human Experience" and by Dr Harold Jeffreys on "Scientific Induction"—and then trying to tell a class of schoolboys what is meant by such phrases as 'cause and effect', 'scientific explanation', or 'error of experiment' (purposely omitting the old terms we used to think so simple, such as 'mass', 'energy', 'atom') Could he possibly assure them that in his teaching 'nothing was taken for granted'?

In every example of scientific experiment which a teacher will give to his pupils, not few but many assumptions will be made, if he is not utterly to bewilder them at this stage. Newton's famous "hypotheses non fingo" is probably largely responsible for the notion that 'nothing is taken for granted' in teaching physical science. The phrase occurs in the penultimate paragraph of the "Principia", it was intended by Newton only to apply to part of his work, and it is in striking contrast with the final paragraph of the "Principia" itself, and with what Priestley calls the "bold", "eccentric" notions of the "Opticks", with its "Queries". The fundamental distinction between verifiable and unverifiable hypotheses drawn by writers like Nunn<sup>6</sup> and Dingle,<sup>7</sup> and the fruitfulness of the great 'unverifiable' hypotheses, such as those of the atom and electron, elevated by some of our most distinguished men of science to the rank of 'ultimate realities'—all these are things which the school-teacher of science ought to have at the back of his mind. To explain them in detail to his pupils would, however, be an impossible task. The 'common-sense' of science is the most elusive of concepts.<sup>8</sup>

While differing from 'H E A' in his views of scientific method, we are in warm agreement with his recent utterances on the artistic aspects of science, aspects of the utmost value to the teacher trying to secure the interest of his pupils. If we agree with Dingle that the material of science consists of the elements of our experience actually or potentially common to all normal people (whereas art and religion are concerned with experiences which may or may not be shared by others), we nevertheless see the *advances* of science have in them something individual, giving to many pupils, if adequately presented, an artistic emotion. In the Report of the British Association Committee of 1917 on Science Teaching in Secondary Schools,

<sup>6</sup> "The Aims of Scientific Method" (1907), pp 129, 130

<sup>7</sup> "Science and Human Experience" (1931), pp 46-50

<sup>8</sup> In his interesting B B C pamphlet on "Science in Perspective" (1931), Prof H Levy gives what he himself terms "the dim outline of a method"

of which Prof Armstrong himself was a member, it is suggested that teachers should not fail to give scope in their teaching to the 'wonder-motive', the 'utility-motive', and the 'systematising motive'. By 'wonder-motive' is not meant the desire to wonder at astronomical immensities or the infinitely small, but at the achievements of individual men in overcoming difficulties, a wonder to be excited as much by the binomial theorem as by the cure for hydrophobia or by wireless telephony. "Execution", says Blake somewhere, "is the chariot of genius". The achievements of genius may be inspiring to many a boy or girl who would be unable to follow a logical analysis of method, of which the author himself may have been unconscious in making his discovery. Prof S Alexander has recently put forward views of which Blake's may be an anticipation.

From these general considerations we turn to another aspect of the matter, not less important. Dr Norwood demands that "windows should be opened in the pupils' minds in all directions". The blindness of the average man to the problems of biology apparent in our educational and administrative systems may, to quote a recent utterance of Dr H H Dale, "become a real danger to our civilisation". "An intelligent appreciation of the fundamental facts of biology is not yet regarded as a necessary part of the equipment of an educated man".<sup>9</sup> About the fact there can be no doubt. The statistics of the School Certificate Examination published by the second British Association Committee under the chairmanship of Sir Richard Gregory, and by Dr Masson, show that only about one per cent of the candidates present themselves in biology or zoology (though a much larger proportion, mostly girls, take botany), and under present conditions the examination-room may be regarded as an approximate reflex of the class-room. There are some schools in which this is not the case, but they are few. We have quoted several authorities in favour of the policy advocated by Dr Masson and Dr Norwood: one other may be cited—the recent Report of the Prime Minister's Committee on the Education and Supply of Biologists, presided over by Lord Chelmsford.<sup>10</sup> "We hold strongly", the Report says, "that no boy should be allowed to leave school without having been introduced to biology" (loc cit, p 23).

Are there in English education at this moment

any powers capable of securing this result? The Chelmsford Committee is conscious of the impotent, not to say ridiculous, delay that has followed the recommendations of its predecessors. The Committee wants steps to be taken by the Board of Education, in concert with the other Government departments. It wants the universities and great public schools to be consulted, but it strangely omits to mention by name the bodies which of all are the most important, if any large number of pupils are to be affected, the local education authorities. Is anything being done? P J H

### Seismology

*Handbuch der Geophysik* Herausgegeben von Prof Dr B Gutenberg Band 4 (Lieferung 1) *Theorie der Erdbebenwellen, Beobachtungen, Bodennunruhe* Von Prof Dr B Gutenberg Pp 298 30 gold marks Lieferung 2 *Seismometer, Auswertung der Diagramme*, von Dr H P Berlage, Jr, *Geologie der Erdbeben*, von Prof Dr A Sieberg Pp 299-686 45 gold marks (Berlin Gebruder Borntraeger, 1929-1930)

PROF B GUTENBERG, a very distinguished seismologist, is general editor and chief author of what our German colleagues call a handbook of geophysics, in ten mighty volumes. There are more than forty other contributors. The two parts under review form the first instalment. The whole, when complete, should be a very comprehensive account of the whole of geophysics, particularly welcome on account of the scattered nature of the literature of the subject.

The first part is entirely by Prof Gutenberg, and half the second by Dr H P Berlage. These cover the whole of instrumental seismology, beginning with the theory of elastic waves, and proceeding to an account of the use of the instrumental records to infer the structure of the earth. The types of seismograph used are described in detail. The accounts given are very full. In places the reviewer might wish them fuller, and a few items are included, with little or no comment, which scarcely seem worth preserving in a work of permanent value. But on the whole we must welcome the most complete account of modern seismology yet published. Very little of any importance has escaped mention and discussion, and the references to original papers in all languages are abundant. This will be the standard work of reference for many years.

The remaining half of the second part, by Prof

A Sieberg, is entitled "Geology of Earthquakes", and deals with macroseismology, or, as the author says, the study of earthquakes in the popular sense—their destructive effects on buildings, the visible effects on the earth's surface features, the movements felt by man, the sea waves produced, and so on. If I devote most attention to this part it is because I have learnt most from it.

The connexion between the local effects in the 'shaken region', that is, the region where motion can be felt, and the movements produced in instruments at a safe distance, has received very little discussion hitherto, and it seems to me that most important advances in both sides of the subject must develop from the study of their interrelations. As a specimen of the degree of separation that exists, it may be mentioned that Dr C. Davison's excellent book, "The Founders of Seismology", contains no reference to Poisson or Rayleigh, who predicted theoretically the three principal types of elastic waves, and Davison might justly reply that none of my own works mentions Mallet or Mercalli. Yet the movement that is felt and in many cases shakes down houses is merely an elastic wave of great intensity, and on the other hand, the waves observed at a great distance have been produced in the shaken region, and must show traces of its properties.

The relation is already becoming an acute problem in instrumental seismology, hitherto we have concentrated attention on the various plutonic layers, but it is becoming clear that the sedimentary layer produces a controlling influence on some phenomena. I hinted very tentatively that some pulses observed in the Jersey earthquake of 1926 might be compressional waves in the sedimentary layer. Tillotson and Maurant have obtained confirmatory evidence, while Stoneley detects signs of an influence of the sedimentary layer on the shorter distortional waves. Now if there are bodily waves transmitted horizontally in the sedimentary layer, the focus must be in that layer. But most continental seismologists (including Gutenberg), in the cases they have investigated, claim to have found foci in the granitic layer at depths of the order of 30 km. I consider these estimates excessive, even on the actual data used, but clearly they are out of the question if the foci are not in the granitic layer at all.

It is here that macroseismology may provide a criterion, and abundant data are given by Prof Sieberg. If the crust were uniform, the intensity would be greatest at the epicentre, and would fall off steadily with distance. This is not confirmed

by observation. There is, of course, a general decrease with distance, but the exceptions are numerous. Usually there are isolated patches of high intensity, in one case (p. 620) the region of greatest intensity actually encloses three separate regions of lower intensity. Sieberg with good reason attributes these variations to differences in the nature and structure of the local sediments. But could they exist if the focus was below the sedimentary layer? The waves at distances comparable with the depth of focus would be incident at high angles on the interface between the sedimentary and granitic layers, and at still higher angles on the outer surface. Great variations in these circumstances seem unlikely. Certainly they are less likely than if the waves felt are transmitted nearly horizontally in the sedimentary layer and subject to its irregularities through the whole of their path. Sieberg does not discuss this point directly, but he contributes much evidence that most earthquakes are due to motion on visible faults, or to infalls of rock in caves, when the focus is certainly in the sedimentary layer, and it does not appear that the seismograms of earthquakes known to be of these types differ from those of the near earthquakes studied in most discussions.

The earthquakes believed by Prof. Turner to have had foci at depths of the order of 300 km. are, of course, in another class, and it cannot be said yet that we have any clear idea as to their cause, but the recent work of Stoneley and Scrase has, at any rate, put their existence on a secure footing.

The book is well and abundantly illustrated, both by diagrams and maps and by actual photographs of the effects of earthquakes. The value of the maps would have been greater if all of them, instead of only a few, had been accompanied by scales of distance.

It is assumed, a little too naively, I think, that the felt intensity and the destructive effect depend only on the acceleration of the ground. In many cases this is probably true, as, for example, in the house shown on p. 572, where the inertia of a too heavy upper story has made it slide horizontally over the lower through about a yard. But there may be cases where the determining factor is the range of variation of velocity, and there must be some where it is the final displacement. C. Haussmann is quoted on p. 612 as finding a displacement of 20 metres in  $2\frac{1}{2}$  years on a known fault, without any earthquake in the usual sense, and therefore negligible acceleration, yet if a building had been over this fault it would have been destroyed as effectively as any in the San Francisco

earthquake. R. D. Oldham's work on this question (*Q. J. Geol. Soc.*, 82, 67-92, 1926) has apparently not come to the author's notice. Again, while too great an acceleration of the ground may break a building fastened to it, it may not throw a man off his feet if it is reversed before he has had time to fall, then the range of velocity will give a better criterion than the acceleration. So far as the criteria agree, they indicate a rough constancy in the period of the motion.

Many and varied are the geographical effects described. On p. 581 is a map of a recent earthquake in Bulgaria, showing the actual development of a miniature rift valley. There are fault scarps, landslips, waterfalls, sand and mud cones, and sea waves. One occasion is mentioned when an earthquake caused a landslip, which blocked a stream and formed a lake, in which mosquitoes bred and led to an epidemic of malaria.

The author is everywhere critical, and his work can be recommended as a stimulating contribution to a complicated subject.

HAROLD JEFFREYS

### The Wild Roses of Central Europe

*Synopsis Rosarum Spontaneorum Europæ Mediæ. Übersicht über die mitteleuropäischen Wildrosen mit besonderer Berücksichtigung ihrer schweizerischen Fundorte.* Von Dr. Robert Keller. (Denkschriften der Schweizerischen Naturforschenden Gesellschaft, Band 65.) Pp. xii + 796 + 40 Tafeln. (Zürich: Gebrüder Fretz & A.-G., 1931.)

THE publication of this monograph marks a definite stage in the history of the taxonomy of *Rosa* and also raises important questions of more general interest. It represents the consistent labours of half a century of the eminent rhodologist, Dr. Robert Keller, of Winterthur, who is to be congratulated on the crowning achievement of his life's work. It is probably the last word on the problem of species in *Rosa* of the purely morphological school of taxonomy before the new genetical taxonomy takes up its inevitable position as an exact science on an experimental basis. In his foreword, Dr. Keller remarks that the parents of the 428 natural hybrids described have been determined morphologically and not experimentally. That expresses in a sentence the fundamental difference between the old and the new taxonomy.

The main object of this Synopsis is, no doubt, to enable collectors to identify and name their specimens. Dr. Keller has achieved this end with distinction, and any wild rose from Central Europe

that cannot be traced in his synopsis of 2407 forms may with high probability be regarded as new to science. There is, however, another important aspect of this monograph which is of interest to biologists as a whole, and that is Keller's concept of a species. Dr Keller, unlike some of his contemporaries—for example, Gandoger, who made 5549 'species' of the genus—has no illusions about the status of the European species, notwithstanding the prolixity of forms that he has distinguished by name. He prefers to take a broader view even than Crépin did in his later years, by reducing the number of Central European species to 26, although, unlike Crépin, he admits 15 subspecies and about 100 varieties and forms of each species.

Except for the subspecies, this is a wise and satisfactory classification. Keller divides the Central European roses into two main groups, *Sociales* and *Arcuatae*, while *Sociales* is further divided into *Erectae* and *Erecto-arcuatae*. In many respects this grouping is natural, although at least 6 of the 22 species in *Arcuatae* are social in root-habit, with erect stems, as in the *Erectae* of the *Sociales*. The 7 sections of the genus with their 6 subsections are natural groups, except that the pentaploid *Stylosae* and the hexaploid *Jundzilliae* might well have been placed as subsections of *Caninae*, and *Eucaninae* divided into two or more subsections.

With a few exceptions, Dr Keller's species appear to be good genetical species, but 7 of his subspecies prove to be equally good species. With regard to nomenclature, Dr Keller in substituting *R. pendulina* L. for *R. alpina* L., *R. glauca* Pourr. for *R. rubrifolia* Vill., *R. eglanteria* L. for *R. rubiginosa* L., and *R. obtusifolia* Desv. for *R. tomentella* Lem., observes the strict rules of priority. He does not, however, substitute *R. Sherardii* Dav. 1813 for *R. omissa* Desegl. 1864 (misprinted "1894" on p. 245) although it is admitted as a synonym, nor does he substitute *R. caesia* Sm. 1811 for *R. Afzeliana* Fries 1816, nor *glaucophylla* Winch 1816 for *vosagrica* Desp. 1828. Dr Keller still maintains the old specific name *R. villosa* L. which was specifically abandoned in the International Rules, and he makes his subspecies facultatively autonomous by repeating the generic initial before the subspecific name.

In citing *R. gallica* L. 1753, instead of *R. gallica* L. 1759, Dr Keller overlooks Crépin's discovery that the original *gallica* of Linnæus of 1753 was a species of *Caninae* and not the familiar plant that Keller describes. Moreover, *R. gallica* L. 1759 is not the earliest name for the plant, since *R. rubra*

Blackw. 1757 precedes it, but the oldest legitimate name for the genetical species is *R. centrifolia* L. 1753, which happens to be the original name given by Theophrastus.

For several reasons it is desirable that the pentaploid species *R. tomentosa* Sm. should be removed from the tetraploid species of *Vestitae*. The hexaploid species *R. Pouzianii* Tratt. should also be separated from the pentaploid *R. canina* L. and the hexaploid species *R. inodora* Fries (*sensu stricto*) from the pentaploid *R. agrestis* Sav.

Dr Keller's 15 subspecies are not so satisfactory as his species. All are in the section *Caninae*, and 7 are regional groups which work out as genetical species, while 2 are common to the whole area, and prove to be genetical varieties. It is now generally recognised that the multitudinous minor variants in *Rosa*, of which Dr Keller describes no less than 2366, each with a set of key characters and a Latin diagnosis, consist almost exclusively of Mendelian segregations following generations of natural crossings of the results of gene mutations and chromosome transmutations within and without the species, leading to almost endless combinations of characters, some dominant and others recessive, some homozygous and others heterozygous. The classification of these minor variants is consequently a matter of extreme difficulty. Dr Keller, in accordance with the Rules of Nomenclature, has made a classification of them into varieties and forms, and recently Christ, Wolley-Dod, and Heslop-Harrison have adopted a similar system. The chief difficulty is that each author has his own opinion whether the same segregate should stand as a variety or a form, and they do not always agree.

It is evident that a standard of classification on genetical lines is necessary for these minor variants of *Rosa*. Engler's idea that the term 'form' should be restricted to a fluctuating somatic modification and Du Rietz's suggestion that the term 'variety' should be confined to local homozygous biotypes (races) seem to be quite impracticable in *Rosa*, and it is hoped that the publication of this monograph will arouse interest among systematists generally so that a satisfactory classification of these minor variants in plants and animals may emerge.

In addition to copious references to authors, synonyms, and geographical distribution, the "Synopsis" contains an ingenious and extensive key to the species, which is made rather unwieldy by the inclusion of parallel varietal characters which are out of place in specific diagnoses. A full analysis of the local distribution of forms in Switzerland is

given, and statistical tables of leaflet numbers are shown under each species. A chapter on the relative fertility and sterility of species and natural hybrids shows the necessity for caution in estimating the percentage of functional pollen grains, and that the complications due to facultative apomixis should also be taken into account. Abstracts of 24 systems of classification of the European roses from 1813 until 1925 emphasise the taxonomic difficulties of the genus. In a chapter on the evolution of species, Dr Keller accepts Tackholm's theory of the origin of the *Caninae* by hybridisation in the Pleistocene period.

Forty excellent coloured plates are issued in a separate binding, which well and truly represent the species and hybrids illustrated. There is a useful and indispensable index, but the synonyms are apparently too numerous to be included. The publication of this important work enhances the reputation of all concerned in its production, and it will no doubt long remain the standard work on the roses of Central Europe. C. C. HURST

### Morphology and Evolution

*Morphologische Gesetzmässigkeiten der Evolution*

Von Prof. Dr. A. N. Sewertzoff. Pp. xiv + 371.

(Jena: Gustav Fischer, 1931.) 22 gold marks.

FOR a quarter of a century, Prof. Sewertzoff and his pupils have been working with the aim of obtaining general principles with the help of which to correlate the present state of knowledge concerning evolution. He came early to the conclusion that this object was most likely to be achieved by a study as detailed as possible of a particular group of animals, for which purpose he selected the vertebrates, paying particular attention to the hard parts so as to be able to make use of palæontology. His book, now under notice, is divided into two parts, of which the first deals with the evolution of the lower vertebrates, the second with the general principles derived from a consideration of such evolution.

In his survey of the history of the vertebrates, Sewertzoff adheres mainly to the generally accepted view. It must be noted, however, that he imagines the early craniates to have had three visceral clefts in front of the hyoid arch. This is one less than he formerly claimed, but it is still one too many, for the evidence from the somites, nerves, visceral arches and clefts, and hypophysis, all points to the premandibular somite (and, therefore, arch) as the original foremost of the whole series.

Sewertzoff departs from custom in contending

that the sturgeons are derived more or less directly from selachian-like ancestors. Space is lacking for a detailed consideration of this point, and it must suffice to say that the evidence which Sewertzoff brings forward does not seem to be adequate to refute the view generally held by the palæontologists of Great Britain, to the effect that the sturgeons are degenerate descendants of the palæoniscoids.

There are a few errors in this part of the book. *Lepidosteus* does not have cosmoid scales, the kidney tubules opening into the pronephric ducts in the early Protocranata were certainly not nephridia, and the nephridia equally certainly did not open into the coelom in the primitive Acrania, seeing that they are closed in *Amphioxus*. But these errors do not invalidate the general lines of Sewertzoff's scheme of vertebrate evolution, which is stimulating if not wholly acceptable. It may be mentioned in passing that while textbooks of morphology are not wanting, there is a need for works on the phylogeny of animals, on the lines of Sewertzoff's sketch.

Coming now to the second part of the book, Sewertzoff makes it clear that he is concerned not with the causes of evolution, but with the manner in which it has occurred, and with the morphological principles involved. He reveals himself as a staunch Darwinian and the whole stage of his thought is set in terms of adaptiveness of organs and of success or failure of organisms in the struggle for existence. He begins by distinguishing two main directions in evolution: the biologically progressive, leading to the production of large groups, rich in sub-groups and individuals, and expansion of range; and the biologically regressive, leading to extinction.

In the biologically progressive direction, Sewertzoff recognises four types or modes: (1) Large changes of general adaptive significance, which raise the degree of organisation of the body and the intensity or energy of the life-processes. Examples of such 'aromorphoses' are the evolution of the brain, sense organs, and heart in the Protocranata, and of the jaws, tail, and paired fins in the Gnathostomes, the lungs, the neck, and feathers of higher forms. It may be noted that aromorphoses do not tie the organism down to any restricted mode of life. (2) Changes which definitely tie the organism to a definite more or less restricted mode of life, without increasing the degree of organisation or of energy output. These changes he calls 'idioadaptations', and holds them responsible for the divergence between rays and sharks, flat-fish and carps, snakes and lizards. Superficial changes of

form and colour also belong here, and a particular aspect of idioadaptation is specialisation. It is to be noted that periods of aromorphosis and idioadaptation may alternate in the history of a group, but the author knows of no case of a group which has undergone specialisation reverting to aromorphosis.

The third and fourth of Sewertzoff's modes are cænogenesis, or adaptive changes confined to early stages of development, and degradation or the acquisition of structures or their loss associated with sessile and parasitic modes of life. It would seem, however, that these categories could conveniently be included in the first two—degradation under idioadaptation, and cænogenesis under idioadaptation or aromorphosis according to the nature of each case.

After an inquiry into the principles which govern the alterations which organs undergo in evolution, Sewertzoff considers the relation between ontogeny and phylogeny. He rejects the Haeckelian view of the pressing back of adult ancestral stages into the young stages of the descendants, and agrees with the view which is constantly gaining favour, to the effect that "evolution is not the alteration of the characters of the ancestral adults, but a modification of the ontogenies of the descendants." As to the time in ontogeny when the evolutionary novelty may arise, Sewertzoff shows that it may be early on, or in the middle, or at the end of the period of morphogenesis, leading to what he calls 'archallaxis', 'deviation', and 'anaboly', respectively. In the latter case, evolution may proceed by the addition of new terminal stages of morphogenesis to the last stage of morphogenesis (not the adult stage) of the ancestor. In this case, the terminal stages of morphogenesis of the ancestors may be repeated, or 'recapitulated'.

The value of this part of Sewertzoff's book is all the greater from the fact that he has purposely made a number of new observations with which to illustrate his points. Such are, in brief, the views which Sewertzoff puts forward as his theory of phylembryogenesis. An interesting question now arises: Is evolution by aromorphosis more likely to occur as a result of the introduction of novelties at the early, middle, or late stages of ontogeny? Sewertzoff does not commit himself on this point.

As a result of a consideration of cases in which the time of appearance in ontogeny of certain evolutionary novelties may reasonably be surmised, it has recently been suggested that the chief characters of the large groups are more likely to have originated as novelties in early stages of development than the reverse. Large groups may also

have characters which arose as late ontogenetic variations, but it is suggested that these are more likely to lead to the production of groups of small classificatory value. In this way it can be understood how the evolutionary capacity of large groups is greater than that of small ones, for, as a rule, the smaller the classificatory value of the group, the more specialised to a particular mode of life are its characters. Sewertzoff himself gives several examples which bear out these views, concluding that major novelties arise by archallaxis, while anaboly leads to the modification of something already present.

Prof Sewertzoff's book is to be warmly recommended as a thought-provoking piece of work, and is all the more valuable because many of the original publications on the subject by himself and his pupils are somewhat inaccessible.

### Progress of Chemistry

*Chemistry at the Centenary (1931) Meeting of the British Association for the Advancement of Science.*  
Pp xi + 272 (Cambridge W. Heffer and Sons, Ltd., 1932) 7s 6d net

THE centenary meeting of the British Association, following on the celebrations of the centenary of Faraday's discovery of electromagnetic induction and preceding the Clerk Maxwell centenary at Cambridge, brought to London a number of eminent foreign visitors which was quite unique in the history of the Association, and is likely to remain unrivalled for many years to come. Although the visitors who came to England to pay honour to the work of Faraday and of Maxwell were primarily physicists, the boundaries between physics and chemistry have been so far obliterated that the officers of Section B (Chemistry) of the British Association were able to make full use of the opportunity which the occasion presented of providing a platform from which the leading workers in atomic physics could speak.

The work of the Chemistry Section included a remarkable presidential address by Sir Harold Hartley on "Michael Faraday and the Theory of Electrolytic Conduction", in which he disclosed the unexpected array of historical material and linked this up with the most modern views on the nature of strong electrolytes. The discussion which followed included contributions from Debye, Bjerrum, Bronsted, Fajans, Philip, Guggenheim, Butler, Scatchard, Lange, McBan, and Lowry. This discussion alone was therefore comparable in

interest with the Faraday Society's general discussion on "Strong Electrolytes" at Oxford in 1927, although it was limited to a single day

The discussion on vitamins on the following day was in some respects even more remarkable, since the visitors who contributed to it must have come to England for this express purpose rather than for the associated physical celebrations. The discussion on vitamin A was introduced by Sir Frederick Gowland Hopkins, and was contributed to by Karrer, Euler, Morton, Heilbron, Richard Kuhn, Moore, and Drummond, while the contributors to the discussion on vitamin B included Jansen, Peters, Drummond, Callow, Windaus, Reerink and van Wijk, Heilbron and Simpson, the concluding review being contributed by Robinson

A symposium on "The British Fuel Problem", with reviews by Sir David Milne-Watson, Sir John Cadman, and Mr H T Tizard, provided a technical alternative to a discussion on the atomic weight of oxygen in Section A, and included contributions from Sir James Irvine and Prof W A Bone

The final discussion, on "The Structure of Simple Molecules", brought into the Chemistry Section many of the pioneers in atomic physics. The contributors to the discussion included Debye, Lennard-Jones, R H Fowler, Victor Henri, Heisenberg, Born, and W L Bragg

In view of the unique character of the programme, it would have been a serious loss not to preserve a permanent record of the work done by the Section. The record provided by the secretaries in the present volume includes all the valuable material contributed to the four discussions. It has been issued in a well-printed volume, comparable in size with the official report of the London meeting of the British Association, and is issued at such a remarkably low price that it should merit a very wide circulation amongst those who are interested in the progress of chemistry in its various aspects

### Short Reviews

*A Practical Handbook of Water Supply* By Dr Frank Dixey Pp xxviii+571 (London Thomas Murby and Co, 1931) 21s net

Few problems of immediate importance in the pioneer development of colonial territories are more urgent than the provision of an adequate water supply. Various geological surveys and irrigation departments give advice on particular schemes, but no book which would serve as a general guide has hitherto been available. Dr Dixey has realised the necessity for such a book as a result of his experience in Nyasaland, and those who are called upon to provide water supplies in

outlying regions owe him a deep debt of gratitude for the very practical and thoroughly competent treatise which he has been stimulated to write

Although the conditions particularly kept in mind are those characteristic of Central and East Africa, the book will prove helpful to workers in other similar regions, and not only so, but also to students of water-supply problems in general, for the geological, engineering, and other aspects of the composite problems involved are all dealt with in ample detail. Methods of dam construction and of sinking wells and bore-holes to moderate depths are described, with the view of helping settlers and administrative officers who are likely to be inexperienced in such work. Less attention is paid to the technique of deep boring, which must of necessity be carried out by experts. The various means of safeguarding against contamination and of purifying unsatisfactory supplies are surveyed in the very important chapter on the quality of water. One of the most interesting chapters is that devoted to water-finding methods. The desirability of a geological report before costly schemes are undertaken is rightly stressed. "Reliance upon any other advice, such as that based on water-divining, may lead to serious waste of time and money." The book concludes with an invaluable summary of the water-supply conditions in South Africa, the Rhodesias, Nyasaland, Tanganyika, Kenya and Uganda, the last of these having been contributed by Mr E J Wayland. There are several geological maps embodying information not otherwise easily accessible

The book will undoubtedly be of very great assistance to those for whom it has been primarily prepared, and much of it will appeal to a far wider audience

*Hydraulics for Engineers including Turbines and Pumps and Unsteady Motion* By Prof R W Angus Pp xii + 304 (London Sir Isaac Pitman and Sons, Ltd, 1931) 12s 6d net

In view of the rapid development of the exploitation of hydro-electric power in Canada and the United States, the subject of hydraulics is of outstanding importance to engineers in North America. A new textbook on the subject by the professor of mechanical engineering in the University of Toronto naturally, therefore, arouses interest as to the treatment accorded to the problems which present themselves in connexion with turbine installations. Including centrifugal pumps, Prof Angus devotes rather more than a third of his book to the consideration of this subject, and within this space gives an effective résumé of the conditions to be met and the calculations involved in design

Among several examples of typical installations, Prof Angus briefly describes the reaction turbines of the Conowingo plant on the Susquehanna River and the impulse turbines of the San Francisquito No 1 plant of the city of Los Angeles. The former, which has a present aggregate capacity of 378,000 horse power, is among the largest in the world, and one of its units is of greater size than any other at present in existence, having a discharge nearly

three times that of the 70,000 horse power turbines at Niagara Falls. This unit, a section of which is illustrated, develops 54,000 horse power under 89 ft head at a speed of 81.8 revolutions a minute. The Los Angeles runner, with a head of 870 ft, develops 32,200 horse power at 143 revolutions a minute, while another (also illustrated) at Big Creek, California, has a capacity of 56,000 horse power at 250 revolutions a minute, under a head of 2200 ft.

The first part of the book deals with the fundamental problems of flow of water in pipes and open channels, through orifices and over weirs, on lines which are fairly general, due prominence being given to the Francis formulæ for weirs and the Ganguillet-Kutter formula for open channels. The third and last part of the book is devoted to non-uniform flow. The type and diagrams are clear and distinct. Exercises are given, with numerical answers, and there is a serviceable index. B C

*Handbuch der Experimentalphysik* Herausgegeben von W. Wien und F. Harms. Unter Mitarbeit von H. Lenz. Band 11, Teil 3. *Elektrische Beleuchtung*, von Dr. Helmuth Schering, *Schwachstromtechnik*, von Prof. Dr. K. Kupfmüller. Pp. xiii + 501. (Leipzig: Akademische Verlagsgesellschaft m. b. H., 1931.) 46 gold marks.

THIS section of the handbook is divided into two parts. The first deals with electric lighting and its measurement, and the second with the techniques of weak currents, including telegraphy and telephony.

Prof. Schering discusses lighting mainly from the scientific point of view, but his results are immediately applicable in practice. Interesting diagrams are given of the energy emitted by substances at various temperatures and how this energy is divided up amongst the rays of different wave-lengths. For measuring mean spherical candle-power Russell's method is given. Apparently in Germany it is possible to buy polar paper divided up into the requisite angles, and this greatly shortens the time taken to make a measurement by this method. Useful data are given in connexion with the Hefner lamp, which has played such a great part in the history of photometry. A good discussion is given of projector lamps. The 'weak current' section of the volume is well done. It is clearly written, the diagrams can be understood at a glance, and it is not overburdened with mathematical equations. A description is given of cables suitable for long-distance transmission. The use of Pupin coils is described, and oscillograms are given to elucidate their action.

*Weeds in the Garden of Marriage*. By George Pitt-Rivers. Pp. xv + 86. (London: Noel Douglas, 1931.) 3s. 6d. net.

It perhaps might have been called more truly "Weeds in the Garden of Race Progress", for the very institution of marriage—as cultivated by Church and State—is one of the rankest weeds Mr. Pitt-Rivers finds. In his own words, his book is "a plea for a little more thinking", and it is backed by forcibly stated reasons for thinking as

he thinks, and for seeing with him that a thoughtful application of the principles of eugenics to our economic and race problems is our only salvation, that, in fact, we are subject to compulsory restriction of reproduction, and eugenics only proposes to change the method of restriction to sterilisation rather than taxation, and shift its operation from the healthy to the feeble.

Mr. Pitt-Rivers is intensely in earnest, for, as Sir Arthur Keith points out in his introduction, he sees disaster stealing upon us, and if he reads the signs of the times aright, there is nothing that can save us. He sees the race, indolent, ignorant, and vain, using its power of reproduction to destroy itself, not only permitting, but even encouraging feebleness and disease to live by mating with intelligence and health, and to send forth new polluted streams, vitalised by that mating. Better, he says, incest and inbreeding than this steady undermining of intelligence and health. Incest gave us Cleopatra, and it would emphasise not only the good qualities of healthy stock but also the defects of the feeble and diseased, until the latter would perish of sheer inanition.

Make the world safe for intelligence, is Mr. Pitt-Rivers' cry, and all good things will be added unto you.

*Creep of Metals*. By H. J. Tapsell. Pp. xiv + 285. (London: Oxford University Press, 1931.) 30s. net.

FOR many years the maximum stress has been regarded by the engineer as the main criterion by which to estimate the strength of a material in service. It is now realised, however, that above a certain temperature the strength may not be truly disclosed by the ordinary tensile test, and a stress, which is often very much less than that which this test would suggest, may result in failure if sufficient time be allowed. The process which brings about fracture is a comparatively slow deformation known as 'creep'. Following on the pioneer work of Chevenard and Dickenson, a very large amount of information has been accumulated on this subject during the past ten years. It is, however, very widely dispersed through engineering and other scientific literature, and the author has performed a most useful service in bringing it together. No phase of the subject has been overlooked and a difficult task has been performed with marked success.

It is clear that as yet little or nothing is known about the ultimate physical explanation of the phenomenon. But the time has now come when it is possible for the author to devote the last chapter of his book to a consideration of the bearing of the facts on the design of structures to operate at those high temperatures at which such effects are most pronounced. In view of the present position of the knowledge of creep, no more than the author has been able to accomplish could possibly be expected, and a most valuable addition has been made to the literature dealing with what is too often the 'no man's land' between metallurgy and engineering. F C T

### The British Association      Some Early Documents

**M**OST appropriately at the time of its centenary, the British Association came into possession of a collection of letters and other documents retained, and in part mounted in a book, by John Phillips, its first secretary. These were saved from destruction and generously presented to the Association by Prof W J Sollas, after they had been unearthed in the department of geology at Oxford, of which Phillips in later life became the head.

By far the most important letter historically is the first—that which Brewster wrote to Phillips in February 1831, proposing the establishment of a 'British Association of Men of Science', and a first meeting in York. The Association possessed until now only a copy of this letter. A large proportion of the letters are acceptances or refusals of invitations to that first meeting—one finds among them such signatures as Whewell, Buckland, Airy, J F W. Herschel, Scoresby, Rigaud, Baden Powell. There are several letters from Robison, who interested himself closely in the details of the arrangements. One observes anxiety as to whether the unsettled state of the country would make it expedient to postpone the inauguration of the Association until 1832—strange that both the birth and the centenary should have fallen in evil days. We have other letters from Brewster besides the first, one of which indicates that he forecast York, as a geographical centre, not only for the first meeting but also for the subsequent headquarters of the Association. We have the essential portion of the letter from Harvey of Plymouth—unfortunately lacking the signature—from which Vernon Harcourt in his foundation speech borrowed, with acknowledgment, the comparison of the objects of the Association with Bacon's 'circuits of divers principal cities' in the "New Atlantis".

An outspoken letter from J D Forbes refers to one received by him from Whewell, who "in mentioning Dr Brewster's attack upon Professors in their scientific character (which his best friends must allow to be unadvised and most unreasonable) adds that even if other circumstances permitted he should certainly not think of going to York, to rally under Dr Brewster's banners. Now this is truly too absurd. That Dr B originated it (*sic*) there can be no doubt however Mr Murchison has endeavoured to confine its origin to London and the Geological Society (and I must say he treated his countrymen rather cavalierly on the occasion)—but to suppose that on that account the Doctor was to take any ostensible charge, so that even if he did a mere party feeling should keep men who ought to be above such things, from joining in a scheme intended for the general promotion of Science in Great Britain, is really vexatious. I believe I mentioned to you that Dr B's nervousness in public is so great that even were he requested, he would be unable to act any conspicuous part at the Meeting. And it might nearly be considered the downfall of the Association, if the whole constellation of talent at

Trinity were thus to be withheld from fostering so infantile a project. I think you might devise some means for correcting the most erroneous views of the Cantabs." Forbes' pen was not prone to restraint, and there is a letter from Brewster to Phillips, quoting with pain some comments by Forbes, in writing to a third party, which injudiciously reflected upon Brewster's candidature for the chair of natural philosophy at Edinburgh, to which Forbes himself was afterwards appointed.

Perhaps the most attractive 'human document' of the collection is the MS report of a discussion on mineral veins, and other transactions, at the Cambridge meeting in 1833. The British Association has never been methodical in reporting its own discussions, and perhaps its reluctance, in earlier days at least, was not unwise, if this be a sample of a serious attempt at a report. Scientifically it is of little worth, save where John Phillips strikes out the reporter's version of his remarks and substitutes his own. The report starts, brightly, with the statement that "Mr John Taylor read a paper on the state of our knowledge with regard to metallic veins, of which not much was audible in consequence of that low tone in which he read and the noise at the other end of the senate house." Sedgwick, as president, was in the chair, and proceeded to summarise the previous speaker's views "as far as he had understood him." Taylor, he said, had referred metallic veins to three causes—"that they were injected from above, or forced up from below by convulsions of nature, or else were what was called contemporaneous, that is made by causes in nature always in operation." Sedgwick remarked that for the results of this last process Whewell ("who had a great penchant for etymology and had larded our language with many words of his own invention") had proposed the phrase "veins of segregation", whereupon Whewell, apparently at considerable length, said nothing in particular upon a topic which was scarcely his own, in justification of his new term, which seemed to find acceptance.

Buckland had previously considered Taylor's three causes, rejecting the first, admitting the second as possible, preferring the third. "He had however some fourth case which I have forgotten," says the reporter naively, "I think it was that of sublimation", and a note is pencilled in Phillips' hand "This was Dr Buckland's favourite theory, by this process he supposed nearly all cases of difficulty could be solved". Not so others. Murchison expressed the fear that Buckland's "brilliant harangue might have silenced some gentlemen present who, he knew, held opinions varying from those which that learned gentleman had expressed." Sedgwick thought some of the distinguished foreigners present might have something to say, and that they were welcome to say it in French if they wished. A pleasant passage follows.

"Mr Murchison. Mr President, I am commissioned by the foreign gentlemen whom you have called upon to speak—"

"President No, no, not called upon no one is called upon to speak—no one need speak unless they please

"Mr Murchison Very well, Mr President, then I am commissioned by the gentlemen whom you have not called upon to say that they are not at present prepared with arguments to refute Dr Buckland's theories but probably may wish to do so at some future time "

Dr Boase then stood forth, and began "in a very angry tone" by saying that he had "not been beaten down by Dr Buckland's speech", and Sedgwick and Murchison had both to assure him that they had never intended to suggest this (and indeed it was sufficiently obvious from what remains to us of the speaker's diatribe) Phillips then took up Whewell's theory of segregation, and by way of supporting it, remarked rather caustically that "he would venture to trespass so far on the attention of the meeting as to state the facts distinctly" One faintly conceives Whewell's own sentiments on hearing this, but the meeting now appears to have concluded peacefully.

The proceedings at the general meeting on the following day seem, however, to have been even less harmonious It opened, following a practice of the time, with reports of sectional transactions by appropriate representatives, and so far all was well Then Peacock read a paper on the analysis of algebra, amid a buzz of conversation which Sedgwick vainly attempted to check at last "the president requested that a constable should be sent up to stand by him", actually, "a servant" was procured Sedgwick by this time may have

been feeling the strain of his office he "observed that Professor Henslow had some proposal which he wished to make to the meeting and he had better speak for himself, as he considered that Professor Henslow knew his own intentions better than he, for he could not understand them at all" Poor Professor Henslow had nothing less innocent to propose than a botanical excursion "He believed the neighbourhood of Cambridge furnished little matter interesting to the geologist, or no doubt Professor Sedgwick would have been happy to—*Professor Sedgwick* Talk of your own affairs if you please, Professor Henslow, and do not interfere with my business" The upshot was that the president, *ex cathedra*, said in effect that the botanists could do as they liked, but if the geologists wanted an excursion, he would rather be excused

Certain further papers were given, including one by Rennie on hydraulics, "much too learned for common comprehension, and not well read" Finally, the president took the floor with a series of announcements, about "the ordinary", about a display of fireworks which "every member was invited to see and take with him a train of three ladies", about a recondite jest of Whewell's concerning waterworks in place of the fireworks, and at last "after several times calling the assemblage back to hear different announcements which he had forgotten, the meeting broke up for that day"

Such, we must suppose, is the earliest attempt to provide brighter reports of the meetings One suspects that the "Mudfog Papers" may have had some basis in reality.

### Physical Laboratories and Social Service \*

By SIR WILLIAM BRAGG, O.M., K.B.E., F.R.S

IN these days the services to be rendered by a physical laboratory become more definite than they were not more stereotyped, because the possibilities and modes of their usefulness are increasing, but more clearly understood With some curiosity I have read again an address which Lord Kelvin (then Sir William Thomson) gave at the opening of the physical and chemical laboratories at University College in Bangor in 1885 Thomson could then describe, as happenings of his own time, the beginnings of instruction in practical physics and chemistry and the construction of the necessary laboratories Soon after he went to Glasgow, in 1846, he was in need of help with some electrical measurements and invited the aid of students, which was willingly given Others heard that some of their fellows had got experimental work to do, and begged to be allowed to join in This was the beginning of practical work for the students in his laboratories Thomson recalled, with great zest, that three-quarters of his helpers were theological students, and that he had to explain to an amazed outsider that they seemed to be happy in their work and were getting on very well

At that time, of course, experimental science had already an accepted place, but there is a quaint evidence of a certain antagonism to it when he carefully explains that to measure the forms and properties of crystals is not to put them to an ignoble use

At that time, also, the Cavendish Laboratory at Cambridge had got well under way, there were laboratories in the London colleges and elsewhere But the number was small in comparison with that of to-day, when so many universities, colleges, schools, industrial firms, and other bodies have built and equipped laboratories, many of them magnificent in their equipments and their spaces The nation itself has felt the need, and in 1899 founded the National Physical Laboratory at Teddington, where, also, a National Chemical Laboratory has now been working for the last few years The research associations working in connexion with the Department of Scientific and Industrial Research have all their separate laboratories where physical and other research is carried on

There has, in fact, been a great change since Thomson made his Bangor speech, in the general estimate of what may and ought to be expected from the physical laboratory People are undoubtedly more interested in the growth of natural

\* From an address delivered at the opening of the new Physics Building of the University of Leeds on Feb 18

knowledge, and more aware of what it means to them. The manufacturer has discovered the possible, and often immediate, advantage of research; the politician observes that scientific discovery is a world force; the teacher and the thinker find that the unfolding of Nature's laws alters the lines on which they move, and many people of every kind ponder over what this continual advance in knowledge may imply.

Moreover, John Citizen is interested in yet another way. There was once a time when private liberality alone founded institutions of learning and provided for their maintenance. Universities, colleges, and schools still owe much to the generosity of their friends. But such institutions are also, in these democratic days, supported directly by the citizen by way of government grants, county grants, municipal grants, and by more widely spread contributions from individuals. Industrial laboratories and State laboratories, of course, are directly provided for by funds which are expected to be repaid in the form of contributions to the welfare of industries and of the community in general. John Citizen has not only become interested as a spectator, in the advance of knowledge by experiment; he has also begun to see its advantage to himself, and is willing to pay for it.

Physics might be thought to be one of the last of the sciences to feel this change of attitude, because it is one of the most fundamental, further away than the others from direct contact with everyday life. Much of modern physics has, of course, an appearance of remoteness. That is not only due to the nature of the subject, but also because various applications of physics have led to hiving-off processes. As soon as a branch of physics becomes useful, it ceases to be physics and begins a new life under another name, such as the various forms of engineering science, or meteorology, or cryogenic research. But there are few things more fascinating in scientific work than the unexpected application of some discovery, made in the progress of a research which seems to be out of touch with everyday things: it may take the form of an illumination of some common event, or a solution of a vexed question, or a welcome aid in some enterprise. Contact is continually being made between the abstruse and the obvious: we should scarcely expect otherwise if we are convinced of an all-embracing unity.

Thus a physical laboratory takes its recognised place of service to the community. What can it do now? How can it extend its service in the future?

First, of course, it exists for the instruction of the student. Many professions for which men and women are trained depend to a greater or lesser extent upon physical laws, which must be grasped and understood. Teaching by experiment can be made an instrument for most valuable training in accuracy, judgment, and the regard for unbiased opinion. Moreover, these young people go out into the world as exponents of ideas and principles which they have learnt to believe in. The great and useful influence which may proceed from a laboratory cannot, in general, be exerted directly: it

has to be disseminated through many channels. In the laboratory it is possible to teach what science is, and what it implies: lessons which are far from being learnt by the world at large. The British Broadcasting Corporation, in its useful, praiseworthy way of attacking the great questions of the day, has recently employed eminent thinkers and workers to speak on "Science and Civilisation." These discourses have been, it seems to me, of great benefit to the cause of science, and not least those which at first sight seem to be antagonistic: for their 'acid' has bitten, not into science itself, but into false conceptions of it, and has left the nobler metal clean and untouched. There are two notable errors which discussions such as these help to remove. One is to mistake mechanisation for science, and to ascribe certain evils to science which come from a wrong use of the machine—which are in truth, as Sir Oliver Lodge says, a blot, not on science, but on civilisation. Splendid truths can be put to evil purposes. The other of the errors to which I would refer is the use of scientific terms, conceptions, and facts in regions where they have no place. I do not mean only arguments about ethers, vibrations, influences, and the like, which few people take seriously; but there is a curious liking for risky extrapolation, for discussions of questions to which experimental science is not yet ready, possibly never will be ready, to give an answer, for argument by analogy, which is dangerous.

A laboratory exists also for the increase of natural knowledge by experiment: and none more obviously so than the laboratory of a university. Of necessity, the most fundamental and valuable research must be done—not as being useless, as some exaggerations would have it—but without regard to the nature, or even the possibility of its use, which is obvious enough. I need not elaborate this vital point: it is well understood.

Of recent years the encouragement of industrial research has led to the establishment of a number of laboratories attached to various industries, and dealing mainly with the physical and chemical problems that industry encounters. These are supplied with men mainly trained in university laboratories. The Department of Scientific and Industrial Research makes a number of grants each year to men working in university laboratories in order that they may be enabled to train themselves for industrial research posts. It is for the university laboratory to encourage and help those who avail themselves of these grants. The university laboratory should be in touch with the surrounding research associations, thus keeping contact between pure science and its special adaptations.

It is possible that there is yet another way in which the laboratory may be of service. I mention it rather as a provocative suggestion than as an actual recommendation. Is it not possible to see more of John Citizen himself in the laboratory? Of late years the science museum has advanced in popularity and usefulness by leaps and bounds. It is far more up-to-date in its exhibits, far more interesting in its displays. The well-organised Science Museum in South Kensington is visited by

far more than a million people a year. A huge museum is in course of erection in Philadelphia. The great museum in Munich is famous. It is, by the way, interesting that this pioneering institution should have been founded in the city where Count Rumford served the State of Bavaria so notably. For it was he who conceived the idea of the science museum and wrote elaborately on its objects and its management. This was a hundred and thirty years ago: and it could not be improved upon now. The Royal Institution was founded in the attempt to give form to his ideas. It failed to do so because the times were not ripe; but that is no longer the case. The Faraday Exhibition of last September drew fifty thousand visitors in the ten days of its activity. I had occasion recently to visit a smaller but similar exhibition arranged in the new laboratories at Exeter; five thousand people visited it in two or three days. The public has not only a newly awakened interest in science, but also is delighted to see actual demonstrations. This is all the better because so much of the interest has been excited by written description or by talks over the ether, and the visible example is much needed as a corrective.

Such exhibitions are of proved value, and may be extremely useful under the conditions of to-day. If any effort were made to follow examples set elsewhere, to demonstrate visually to John Citizen the slow unfolding of Nature's laws by patient research, the discovery of unsuspected beauties of order and adaptation, the origin of new conceptions of the universe, and, not least, the skilful handling of new knowledge for the service and delight of man, then the university laboratories would naturally be looked to for help. To them it would fall, as it fell to the Royal Institution, to illustrate particularly the development of scientific ideas and methods.

We cannot ask that everyone shall be trained to understand and follow the advance of scientific knowledge. All that can be worked for—and it is far from our present attainment—is that there shall be an understanding of what science is, of what it can do, and of what it cannot do. Even this cannot be expected from the public as a whole: but it is urgently necessary in these days that a sufficient number shall be so informed, and especially those whose collective opinions and wishes determine the general courses of action.

### Clouds High in the Stratosphere

By Prof. S. CHAPMAN, F.R.S.

THREE years ago, Prof. C. Størmer, of Oslo, made a preliminary announcement in NATURE of photographic observations by himself and his assistants upon the height and colour-distribution of some clouds at a remarkably great height in the atmosphere nearly over Oslo.<sup>1</sup> He has now issued a detailed account of this work,<sup>2</sup> and also of some hitherto unpublished visual observations on similar clouds, made by him on Jan. 1 and Jan. 15, 1890. The memoir is very fully illustrated by 140 diagrams and eleven beautiful photographs, three of which are reproduced herewith.

The clouds were of the type termed in English iridescent; in German, the language in which Prof. Størmer's memoir is written, they are called *Perlmutterwolken* (mother-of-pearl clouds). The simile appears to be an apt one for the more luminous parts of the clouds, which present one of the most beautiful spectacles afforded by the sky. The colours and colour changes observed in these clouds are stated to be "essentially different" from the ordinary iridescence often seen at the edges of thin clouds near the sun. They are also very different from the bluish whiteness of the luminous night clouds, at about 80 km. height according to Jesse, which Størmer states have often been seen by him. Very detailed descriptions are given as to the changing colour distribution of the clouds, especially for those of January 1890; the colours are mainly arranged in bands following the outlines of the clouds, and these bands, and the outlines, in some cases change rapidly, so that before a sketch of them is completed the earlier part of the sketch no longer represents the form of that section of the cloud.

Apart from their extreme beauty, the clouds

are distinguished for their great height; this was suspected by the late Prof. H. Mohn, who specially studied these clouds, but it was first definitely confirmed by Prof. Størmer in 1927, who was able, on Dec. 30, 1926, to take two pairs of simultaneous photographs of such clouds from his auroral stations at Oslo and Oskarsborg. The height found was between 26 km. and 30 km. The new photographic material for the clouds of Jan. 13, 1929, is much more ample, the number of pairs of photographs exceeding ninety. The heights then found lie between 23 km. and 26 km. The existence of clouds at this high level had never previously been established. Ordinary clouds are almost entirely confined to the troposphere, that is, below about 10 km. These mother-of-pearl clouds are high up in the stratosphere.

Yet another peculiarity of these clouds is their rarity; Prof. Størmer saw them in 1890, but from 1892 until the end of 1926, though carefully watching for them, he failed to find any. In 1929 he again saw them. The conditions under which they were seen were similar in the three cases, and agreed with those described by Mohn, as associated with nearly all his observations of the clouds. They occur when there is a deep barometric depression near Oslo, and usually to the north; owing to the distribution of the mountains in the adjacent region, warm dry winds (Föhn) then often blow down the southerly and easterly slopes towards Oslo, and produce high temperatures, and a clear sky, over a part of the cyclonic area which is usually overclouded. Hence Størmer suggests that the high clouds may in fact be common features in the stratosphere over the ascending part of cyclones, but usually invisible. If this

FIG. 1.—Iridescent clouds to the west-north-west, after sunset on Jan. 13, 1929.

FIG. 2.—Iridescent clouds to the west-south-west, on Jan. 13, 1929.

suggestion could be tested by aeroplane observations above the clouds during cyclones (though this may offer great difficulty) it would be of great interest.

Visual observations of the clouds seen in December 1926 indicated the very high velocity of 75 metres a second (170 miles an hour). Those of January 1929 were nearly stationary, though near the ground there was a strong north-westerly wind; "the mother-of-pearl clouds lay over Ostland [a district near Oslo] for a time longer than that needed by the lower air to travel from southern Norway to Germany". Those of January 1890 seemed to be nearly stationary as a whole,

a second, during the  $1\frac{1}{4}$  hours of duration. If this be interpreted as their steady rate of fall subject only to gravity and the resistance of stationary air, it enables the size of the cloud particles to be estimated roughly, assuming that they have the density of water and are spherical. Applying Stokes's formula, the result is 0.005 cm. radius, but this value is near the upper limit for which, in these circumstances, Stokes's formula is applicable. The radius of ordinary cloud particles is about 0.001 cm. It is, of course, uncertain whether the substance forming the mother-of-pearl clouds is water, though it is difficult to see what else it could be. Iridescence is currently interpreted as

FIG. 3.—Iridescent clouds to the south-west, on Jan. 13, 1929.

but, like those of 1929 (though in a higher degree), they showed rapid internal motion, constantly breaking up or changing their shape. This is of interest as tending to confirm the view that convection or eddying motion does not cease at the top of the troposphere, but may extend far up into the stratosphere, at least to a sufficient degree to maintain a uniform mixture of the permanent constituents of the air up to a considerable height. Hitherto the most direct support for this idea has been the distorted meteor trails sometimes observed, generally at greater heights than 30 km. Prof. Størmer's observations on these high clouds of 1890 seem to afford valuable independent confirmation of this view.

The photographs of one small cloud, of January 1929, indicate a slow velocity of descent, of 30 cm.

indicating the presence of supercooled waterdrops.

The physical implications of the presence of these clouds at their considerable height in the stratosphere are, and for some time may remain, obscure; but possibly they will play a significant part, along with such other remarkable facts as those of the ozone relations with surface weather, in unravelling the mysterious and important problem of the origin of cyclones. However this may prove, Prof. Størmer is to be congratulated on this new achievement in precise upper atmospheric investigation, an interesting and important by-product of the organisation he has built up for the study of the aurora borealis.

## News and Views

**Bicentenary of David Rittenhouse**

ON April 8 occurs the bicentenary of the birth of David Rittenhouse, the American astronomer, who has been described as "a true product of American genius and toil, and the highest embodiment of the pioneer spirit in science during the colonial period". The eldest son and the third child in the family of a farmer of Norriton, about twenty miles from Philadelphia, as a boy he began work on the land, but the gift of some tools and mathematical books stimulated his interest in mechanics and science. While still a youth he set up as a clockmaker, and at twenty was studying Newton's "Principia". Though in after years he devoted much time to mathematics and physics, his first important work was in astronomy. He made the first transit instrument and the first orrery constructed in America, in 1768 began the erection of an observatory at Norriton, and the following year took a prominent part in observing the transit of Venus. One of the earliest members of the American Philosophical Society, he contributed nineteen papers to its *Transactions*, in 1775 he delivered an oration on the history of astronomy, and, on Franklin's death in 1790, was chosen president. From 1777 until 1789 he was treasurer of the State of Pennsylvania, and from 1792 until 1795 master of the Mint of the United States. He received honorary degrees from Harvard, Princeton, and Pennsylvania Colleges, and in 1795 was elected a fellow of the Royal Society. His death took place in Philadelphia on June 26, 1796, and he was buried in the Presbyterian churchyard in that city.

**Dr. N. E. Brown**

THE University of the Witwatersrand, Johannesburg, has conferred the honorary degree of D.Sc. on Mr. N. E. Brown, formerly assistant in the Royal Botanic Gardens, Kew, in recognition of his work on the South African flora. At the request of the Moss professor of botany in the University, and to mark the conferment of the degree, Sir Arthur Hill formally presented Dr. Brown to his old colleagues in the Herbarium of the Royal Botanic Gardens, Kew, on March 19. In the course of a short address, Sir Arthur said: "Dr. Brown was on our staff for forty-one years, from 1873 until 1914. He was elected an associate of the Linnean Society in 1879, and in 1921 he received the Senior Captain Scott Medal for scientific research in South Africa from the South African Biological Society. I need not detail his many contributions to South African botany, as they are so well known to all botanists, but it is interesting to record that the following eminent South African botanists warmly supported the proposal that Dr. Brown should be honoured by South Africa: Gen. the Right. Hon. J. C. Smuts, Dr. I. B. Pole Evans, Prof. J. W. Bews, Prof. R. S. Adamson, Prof. R. H. Compton, and Dr. John Muir."

**Taxation of Imported Books in Australia**

As recorded in NATURE of Feb. 20, p. 271, a deputation representative of national libraries, universities, professional institutions in Australia and the Council

for Scientific and Industrial Research waited on the new Prime Minister, Mr. Lyons, early in February and pleaded for remission of the emergency taxation on imported books imposed by the late Labour Government. The revenue from this source in the current financial year ending on June 30 is estimated at about £75,000 from primage tax and £55,000 from sales tax. It was urged that the continuation of these taxes would result in a far greater loss in efficiency to the whole community than a loss of £130,000 would represent to the Government. Book prices are now so high that students are being forced to cease purchasing technical works and to rely more on libraries; but, unfortunately, the libraries are failing them. That in Sydney, for example, was obliged recently to cease its subscriptions to no less than 100 journals, and in the near future it is feared that a further 150 will have to be sacrificed. Other striking examples of the unhappy results of this taxation were quoted. Mr. Lyons, in reply, agreed with all the main contentions of the deputation, and offered slight relief in cases of exchange publications and certain historical materials for libraries. For the rest, he frankly pointed to the disquieting financial position of the Commonwealth and asserted that attainment of budgetary equilibrium is the only hope for universities, scientific societies, and the whole country. The book tax revenue must remain for the present. Sheer necessity is driving the Government to this unfortunate device, and to others also, which admittedly and inevitably will to some extent undermine the efficiency of the nation. Such a reply, while quite understandable, leaves a serious problem to be faced by educational and scientific organisations in Australia.

**New Emulsion Sensitive to the Infra-red**

FOR some time past, photographic materials sensitive to radiation between 7000 Å. and 9000 Å. have been available. The sensitivity of these plates has, however, not been high. The Ilford Company has now produced a plate which possesses a comparatively high sensitivity for this region of the spectrum. With a subject illuminated by two 1500-watt gas-filled lamps at a distance of about eight feet and screened by filters cutting off radiation of shorter wave-length than 7000 Å., the exposure is about half a second with the lens working at *f*. 4. Such photographs, taken in the dark, serve as an excellent demonstration of the existence of invisible radiation; the public, already accustomed to the idea of ultra-violet rays, thus becomes familiar with the infra-red. The practical use of these plates is, however, considerably greater than that of demonstrating the actinic power of the infra-red: in astronomical and geographical recording, their power to respond to the unscattered radiation coming through mist and haze from very distant objects makes them particularly valuable.

**The Sherman Hoyt Cactus House, Kew Gardens**

THE outstanding feature of the Royal Horticultural Society's Show at Chelsea in May 1929 was the

exhibit of cacti and other succulent plants which was shown by Mrs A Sherman Hoyt, of Pasadena, California. The collection of living plants was arranged against a painted scene of the Mohave Desert, and the whole exhibit was a presentation of the desert flora of Southern California. At the close of the Show, Mrs Sherman Hoyt very generously presented the collection of living plants to Kew, together with the painted desert scene and the rock and sand which she had brought over from California. Since it was impossible to make an adequate display of her exhibit or to make use of the very beautiful painting in any of the houses at Kew, Mrs Sherman Hoyt most generously offered to build a special house for the display of her plants with the background. In the house, now completed and planted, the desert scene occupies the semi-circular wall of the apse, and in the foreground is a representation of the desert in conformity with the painted background. The stone which has been used for building up the foreground is old red sandstone from Dunster, Somerset, and matches remarkably closely both in colour and structure the Californian rocks shown in the picture. Cacti and other succulent plants have been placed among the rocks in positions as near as possible to those in which they are found in their native home, and the whole effect makes a remarkably striking picture, since the rocky foreground blends so naturally with the painted desert scene behind that it is by no means easy to detect any break between the actual living plants and those shown in the background. The house was opened to the public on March 24.

#### India and Babylonia

THE discoveries at Tell Asmar (Eshnunnu or Ash-nunnak), announced by Dr H Frankfort in his letter to the *Times* of March 26, constitute an addition of no little importance to the evidence linking up the early civilisations of Mesopotamia and the Indus valley, especially if his conjectural relation of the new finds to the culture of Mohenjo Daro should be confirmed by subsequent investigation. The excavations of the Oriental Institute of Chicago on the site of private houses of the age of the Dynasty of Akkad (c 2550 B C) on the northern outskirts of the Tell have brought to light two seals, of which the character points unquestionably to an Indian origin. One, a cylinder seal, shows a design of a procession of animals, elephants and rhinoceros with crocodiles, which in subject and convention is both alien to Mesopotamia and referable to the Indus civilisation, while the second is of more common Indian form, a square stamp seal with a pierced knob on the back, and bearing a design of concentric squares which does not appear elsewhere in Mesopotamia, but occurs on similar seals at Mohenjo Daro. Further evidence pointing in the same direction has been found in the form of etched carnelian beads resembling Indian specimens, kidney-shaped inlays of bone identical in shape with some in shell from Mohenjo Daro, and two sherds of pottery showing a decoration with knobs, unknown in Mesopotamia, but also occurring at Mohenjo Daro. Certain distinctive features in the seals, however, lead Dr Frankfort

to think that either they belong to a slightly earlier or later phase of Indian civilisation than that at Mohenjo Daro or they may have come from another site within the same cultural area, the latter alternative being the more probable.

#### Bird-ringing in Great Britain

THE banding or ringing of birds is now accepted as the established technique for elucidating migratory and other movements, and Mr H F Witherby and the *British Birds* scheme are to be congratulated upon the success with which they have kept the system alive and increasingly flourishing in the British Isles. During 1931, more British birds than ever were marked with identification rings, 29,554, and this brings the grand total since the beginning of the scheme in 1909 to 316,955 (*British Birds*, March 1932, p 286). Recoveries vary greatly amongst the different species: the highest percentages are shared by two birds of prey, the peregrine falcon (23.3 per cent) and the merlin (21.8 per cent), and these figures suggest the intensity of destruction which overtakes such birds at the hands of game-preservers, for even the innocent kestrel is represented by 49 returns out of 494 ringed. At the other end of the scale stands the blackcap, the 517 ringed individuals of which gave not a single return, and for all the warblers and even many of the finches the recoveries are very meagre. Of 496 nightingales only 2 have been handled again, and of 507 arctic terns only one. It is obvious that a great deal of labour goes unrewarded in ringing birds, 22,943 swallows have yielded only 163 (0.7 per cent) returns, but the returns have brought out new facts regarding the range of the southward migration and the return of the birds to the locality of their birth. More curious still, of 37,225 song-thrushes, only 481 or 1.4 per cent have been found again.

#### The Nature of Carpels

IN a preliminary notice (*Bull. Classe des Sci. (Acad. Roy. de Belgique)* 5<sup>e</sup> Série, tome 17, 1931), Grégoire has criticised the view of the foliar nature of carpels, and in a fuller treatise he proposes also to extend the argument to the comparison of stamens with leaves, and, in fact, of the flower with a vegetative bud. His criticism is based on ontogeny, he points out that when carpels are formed, they do not appear as lateral structures on the floral axis, and the apex of the latter can never be recognised as still persistent in the centre of the flower. Further, he considers that the margins of the carpellary upgrowths do not meet and fuse marginally as is usually supposed, but are merely the appearances due to the upward extensions of a split in the tissues of the lower part, as this expands to form the cavity of the ovary. Most botanists agree, however, that the comparative morphology of vegetative and reproductive shoots supports the general view of the homology of vegetative bud and flower, but the changed type of growth has so altered the floral parts that, the nearer one passes towards the centre of the flower, the more difficult does it become to press detailed comparisons.

### Cultivation of Bulbs

DURING recent years, bulbs have become a field crop of considerable importance, especially in the Scilly Isles, Cornwall, and Lincolnshire, and growers, or intending growers, will welcome the illustrated bulletin No 44, entitled "Narcissi Culture", recently issued by the Ministry of Agriculture (H M Stationery Office, 9d). Although bulbs grow well on a number of soils, good drainage and cultivation are essential, but the direct application of fresh manure should be avoided. Potatoes which have been adequately manured leave the soil in excellent condition for bulbs. Among some of the more important questions upon which advice is given are those relating to grading, lifting, storage, and planting. Eelworm has become a serious menace to the bulb-grower, and sterilisation by means of hot water (three hours' immersion at 110° F) is strongly advocated, the treatment being given when the bulbs are in as dormant a condition as possible, or injury may result. As regards flowers, while good grading, bunching, and packing are essential, the importance of making the flowers look attractive by means of details such as packing-paper should not be overlooked. Although this trade in narcissus flowers has increased so enormously, the allied bulb-growing industry could become one of even greater financial importance, for the sum spent annually on imported bulbs amounts to nearly £1,500,000.

### Manures and Manuring

It is recognised that owing to the variation in local conditions, it is impossible to give a complete guide to manuring on every farm. Still, the information supplied in *Bulletin* No 36, entitled "Manures and Manuring", which has recently been issued by the Ministry of Agriculture to replace the sectional volume of *Leaflets* No 8 on the same subject, the text having been considerably revised by Mr H. V. Garner (H M Stationery Office, price 1s 3d net), should be of the utmost value to farmers, if they are to derive the fullest benefit from the money spent on fertilisers. The *Bulletin* is divided into three parts, the first of which deals with organic manures. In spite of the recent great development in artificial fertilisers, farmyard manure is still the stand-by of arable farmers, but although it is by far the most important type of organic manure, the value of other materials such as liquid manure, town refuse, poultry manure, and seaweed is evidently considerable. Part II is devoted to artificial fertilisers. The various types of nitrogenous, phosphatic, and potash manures now on the market are described, while a further section deals with the use of compound manures. The third part supplies useful information with regard to the purchase and use of artificial fertilisers, and enables the farmer to determine the comparative value and costs of nitrogen, phosphoric acid, and potash in the different forms without difficulty. Some suggestions are made, on quite general lines, as to the treatment of farm crops, and a further section is devoted to a discussion of soil analysis and its bearing on cropping and manuring.

No 3257, Vol 129]

### Improvements in Epidiascopes

RECENT developments in the design of instruments for the projection of opaque objects have been directed towards increasing the intensity of light directed on the object, improving the quality of the projection lens, and simplifying the mechanical construction in order to ensure lightness, durability, and ease of manipulation. An active part in the development and perfecting of such instruments has been taken by Messrs Newton and Co of 72 Wigmore Street, London, W1. Since the production of their first episcopes in 1916, the efficiency and convenience of succeeding models have increased with each stage of development. The high efficiency of their latest types is due largely to the use of special diffusion reflectors. The illuminant is a single 500-watt gas-filled lamp which is so placed that four of these reflectors can be used to concentrate the light on the object and give a uniform illumination over the whole field, an area 6 in x 6 in. This arrangement, combined with a large aperture projection lens, provides an illumination on the screen equal to that obtained from earlier instruments employing two lamps. As only one lamp is used and the lamp-house well ventilated, the objects are not exposed to any great heat. When it is necessary to keep them at room temperature a ventilating fan can easily be fitted. The silver-surfaced reversing mirror is mounted outside the lamp-house and, consequently, is not subjected to heating from the lamp. The construction of the body, which is of cast aluminium, is such as to ensure lightness and durability, and the design of the instrument renders its operation extremely simple. Precise and easy adjustments are provided for all necessary movements. Instruments of different sizes, embodying these improvements, are available with working distances ranging from 16 ft. to 40 ft.

### Electrical Conveyors in Mines

It is generally admitted that the only real way to increase the prosperity of a coal mine is to increase the output per head of the workers employed. Of recent years great improvements have been made in the methods of the removal of the coal broken at the working face by mechanical conveyors actuated by electric motors. The Metropolitan-Vickers Electrical Company has specialised in the production of motors and control gear for this purpose. In the December issue of the firm's *Gazette*, an account is given of the many rigorous conditions these motors have to satisfy and the various types of conveyor used in practice. In the belt conveyor the coal is carried on a moving continuous belt. In the shaker conveyor it is conveyed by an oscillating trough, which moves slowly in one direction but has a comparatively quick return. The coal is thus carried forward in the desired direction by a series of jerks. In the scraper conveyor the coal is conveyed by a continuous scraper working in a fixed trough. For each type of conveyor the demands on the electrical motor are different and so also are the arrangements of the electrical control equipment. Graphs are given, showing how the loads on these types

of conveyor vary with the time. In the motors ordinarily used, causes of failure arise from the whipping of the shaft and from the ingress of stone dust at the bearings. In the motors described, the roller-bearing at the driving end and the ball-bearing at the opposite end are both constructed in dust-proof ' housings '. The diameter of the shaft of a Metropolitan-Vickers new 15-h p. conveyor motor is 2.5 in. and the rotating part is practically indestructible. The progress made in mechanical haulage will greatly diminish the use of animals underground for haulage purposes.

#### British High-Speed Aircraft

THE Aeronautical Research Committee has recently issued a résumé of the original scientific work done by various authorities in Great Britain upon the development of racing seaplanes, which has led finally to the winning outright of the Schneider Trophy and the breaking of the world's speed record during September 1931 (*Reports and Memoranda*, No. 1300 "Collected Reports on British High Speed Aircraft for the 1927 Schneider Trophy Contest", by W. L. Cowley. London: H.M. Stationery Office). This is a departure from the normal procedure of issuing information in disconnected reports and memoranda as it becomes available, which has the advantage that it becomes virtually a textbook upon its subject and saves the labour necessary in hunting up such information when issued in separate pamphlets. On the other hand, if it is necessary to wait for more than four years for the collection and collation of such information, the advantage of its more convenient method of issue is largely outweighed by the obsolescence of its material. The subject matter is divided into separate headings of research, specifications, design and construction, inspection and test, and operational. It deals in great detail with three machines that are widely different in characteristics regarded from the point of view of high speed flight. The monoplane versus biplane, and the air-cooled versus water-cooled engine controversy is thoroughly fought out with representative machines of each class. The most significant thing about the report is the agreement between scientific prediction and actual results, and the ability of scientific investigation to explain apparent phenomena arising during practical use of the aircraft.

#### Nickel in Marine Engineering

THE January issue of the *Transactions of the Institute of Marine Engineers* contains, as usual, a selection of important articles from the technical press, and a report of a paper on "Nickel and Nickel Alloys in Marine Engineering", read to the Institute by Mr. J. McNeil on Dec. 8. Of all the many uses to which nickel has been put aboard ship, none has proved more valuable than when alloyed with copper for condenser tubes. For a very long period, the deterioration of brass condenser tubes, with its accompanying trouble through leakage of sea water, has been a very serious problem, especially in ships fitted with water-tube boilers, but it appears to have been solved at last by the use of an alloy of 70 per cent copper and 30 per

cent nickel for the tubes. Alloyed with both ferrous or non-ferrous metals, nickel is used for steam turbine blades and nozzles, high-pressure steam valves and fittings, propellers, pistons and liners of Diesel engines, reduction gear wheels, and even crankshafts. Recently a process has been evolved in which nickel can be deposited in thick layers and thus worn parts built up. There is remarkable adhesion between steel and deposited nickel, and the resistance to shear of a thick ring of nickel deposited on steel is stated to be practically that of the metal itself.

#### Arctic Exploration

MUCH activity in polar exploration during the last year, particularly in Greenland and Northern Land and adjacent islands, is noted in the *Polar Record* for January. When Nansen crossed Greenland in 1888, the journey was considered to be difficult and adventurous. Since that date several other crossings have been made, but no period has been so fruitful in the exploration of the ice sheet as 1930 and 1931. During that time, two observatories have been instituted and used for longer or shorter periods on the ice, including the German station of the Wegener expedition in the centre, three new crossings of the ice-sheet have been made, including one across the greatest width, and for the first time, echo measurements of the thickness of the ice have been taken. It is also noted that Soviet explorers from the station on the Kamenev Islands to the west of Northern Land, in long sledge journeys, have filled in the western coasts of that land and determined its northern extremity in lat. 83° 16' N, long. 95° 37' E, thus finishing the last piece of pioneer work that the arctic regions offered. Details of these and various other polar explorations are given in the journal.

#### The Malabar District of India

A SERIES of articles on the Malabar district of India is published in an enlarged number of the *Journal of the Madras Geographical Association* (Oct. 1931-Jan. 1932). These papers were read at a conference of the Association held at Palghat in May 1931. They cover the geology, meteorology, botany, and agriculture of the district, and are illustrated by various maps. Following these there are other papers dealing with modern and ancient trade, trade routes, and urban centres. A particularly interesting paper treats of Roman trade centres on the Malabar coast. There are also notes on the place names. The volume is a useful contribution to the study of India, and is chiefly the work of Indian teachers.

#### Tours in the U.S.S.R.

IN 1931 the Society for Cultural Relations arranged two conducted tours to demonstrate present activities in science and medicine in the U.S.S.R. Similar tours, each lasting about a month, are being organised this year between July 15 and Sept. 15. It is hoped to arrange parties for physicists, biologists, medical men, and others, each party being limited to about twenty persons. Travelling arrangements will be made by Intourist, Ltd., Bush House, Aldwych, W.C.2, and

competent guides and interpreters will be provided by "Voks", the Soviet organisation for cultural relations with foreign countries. Full particulars can be obtained from the Society for Cultural Relations, 1 Montague Street, London, W C 1

#### Royal Institute of Public Health

THE annual Congress of the Royal Institute of Public Health will be held in Belfast on May 10-15, under the presidency of the Marquess of Londonderry. The Congress will be divided into the following Sections: I, State Medicine and Municipal Hygiene, II, Industrial Hygiene, III, Women and Children and the Public Health, IV, Tuberculosis, V, Pathology, Bacteriology, and Biochemistry. The inaugural meeting will be held in the Great Hall of Queen's University, at 11 A.M. on May 10, when the presidential address will be delivered. Several general excursions have been arranged, besides sectional visits to hospitals, sanatoria, etc., and certain institutions, centres, and works will be open for inspection. Further information can be obtained on application to the Secretary, Royal Institute of Public Health, 37 Russell Square, London, W C 1

#### Anti-Malarial Measures

SIR MALCOLM WATSON stated at a meeting held in January of the Industrial Anti-Malarial Advisory Committee of the Ross Institute for Tropical Diseases that while Paris green has a place in malaria control, it is not a substitute for oiling surface waters that breed mosquitoes, for the female can safely lay its eggs in water treated with Paris green, but is killed by water that has been oiled. The nature of the crude oil forming the basis of anti-malarial oiling mixtures has an important bearing on efficiency, and Dr Ramsay, in association with the Burma Shell Group, has completed researches upon the oils best suited for such mixtures.

#### Joint Archaeological Expedition to Antioch

ARRANGEMENTS have been made, we learn from Science Service, Washington, D.C., between Princeton University, New Jersey, and the Musée National of France, the Baltimore Museum of Art, and the Worcester Art Museum, for a joint expedition of excavation at Antioch. A five-year programme of excavation has been arranged. Prof. George W. Elderkin, of Princeton, is leaving immediately for Antioch to initiate the work. It is expected that it will be possible to excavate this ancient city without any disturbance of existing buildings.

#### Announcements

WE much regret to announce the death, on March 26, at the age of seventy-seven years, of the Right Hon. Sir Horace Plunkett, K.C.V.O., F.R.S., first vice-president of the Department of Agriculture and Technical Instruction for Ireland and a pioneer in the organisation and development of Irish agriculture.

At the March meeting of the Council of the Institute of Actuaries, Mr. W. Palin Elderton was elected president to succeed Mr. H. M. Trouncer, whose term of office expires in June.

No 3257, Vol. 129]

MR. ALDOUS HUXLEY will deliver the Huxley Memorial Lecture at the Imperial College of Science and Technology, South Kensington, London, S.W. 7, on May 4, at 5.30 P.M. The subject of the lecture will be "Huxley as a Literary Man."

At the annual business meeting of the Royal Philosophical Society of Glasgow, held on March 23, the following officers were elected: *Vice-President*, Dr. Henry L. G. Leask, *Hon. Librarian*, Dr. James Knight, *Hon. Treasurer*, Sir John Mann, *Secretary*, Mr. John A. Buyers, *Members of Council*, Mr. John P. Heshin, Miss M. A. Hannan Watson, and Mr. George B. Wishart.

LORD WAKEFIELD has given a sum of £25,000, spread over seven years, as a contribution to the Imperial Institute. The Institute is financed by annual grants from the Treasury, the Dominions, India, and the Colonies, and was faced with the prospect of curtailment of its activities, owing to temporary reduction of some of its supporting grants. It is hoped that Lord Wakefield's gift will enable the Imperial Institute to tide over the period of difficulty.

A COURSE of three public lectures on "The Role of Statistical Method in Industrial Standardisation" will be given by Dr. W. A. Shewhart at University College, Gower Street, London, W.C. 1, on May 3, 5, and 6, at 5.30 P.M. Dr. Shewhart is a member of the technical staff of the Bell Telephone Laboratories, New York, and in these lectures an attempt will be made to outline the present status of the applications of modern statistics. A syllabus of the lectures may be obtained on application to the Academic Registrar, University of London, South Kensington, London, S.W. 7.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A public librarian under the Colwyn Bay Urban District Council—The Clerk to the Urban District Council, Council Offices, Colwyn Bay (April 14). An assistant curator in the Royal Botanic Gardens, Kew, in charge of the Decorative Department—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W. 1 (April 15). A mathematical master at the Royal Naval College, Dartmouth—The Headmaster, Royal Naval College, Dartmouth (April 18). A professor of philosophy at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (April 20). An assistant in the Natural History Department of the University of Aberdeen—The Secretary, University, Aberdeen (April 20). A reader in chemical engineering at the Imperial College (Royal College of Science)—The Academic Registrar, University of London, South Kensington, S.W. 7 (April 22). A professor of zoology at Armstrong College and director of the Dove Marine Laboratory—The Registrar, Armstrong College, Newcastle-upon-Tyne (April 23). A whole-time radiologist at the Johannesburg Hospital—The Superintendent, Johannesburg Hospital, Johannesburg, South Africa (May 25). A male laboratory assistant at the Government Experimental Station, Porton—The Commandant, Experimental Station, Porton, near Salisbury.

## Letters to the Editor

## Atoms and Molecules as Fitzgerald Oscillators

ACCORDING to the theory of the Raman effect, the depolarisation  $\rho$  of the Raman lines in gases and liquids should, when observed at right angles to the natural incident light, never exceed the value  $\rho = 6/7$ . Whilst values of  $\rho \geq 1$ , which have frequently been observed, could be ascribed to observational errors, a value of  $\rho = 2$ , which has been estimated by Bhagavantam<sup>1</sup> for one line of liquid sulphur trioxide, called for a further investigation. I have carried out this work,<sup>2</sup> using polarised incident light with the electric vector perpendicular to the plane through the light source, scattering object and observer. Denoting by  $\sigma$  the depolarisation for this mode of observation, there exists between  $\sigma$  and  $\rho$  the relation

$$\sigma = \frac{\rho}{2 - \rho}$$

It is clear, that, whilst the theoretical limit for  $\sigma$  is  $3/4$ , one should get  $\sigma = \infty$  in the case cited by Bhagavantam. This was clearly disproved by the experiment, which gave a value of  $\sigma$  not exceeding unity.

Sir C. V. Raman has lately made<sup>3</sup> the very original suggestion that the observed values of  $\rho > 6/7$  might be explained theoretically by assuming that the scattering molecules behave as magnetic dipoles. If this be the case, it is the magnetic vector in the incident light which gives rise to the Raman line, consequently the above-mentioned experiment must be repeated with the incident light polarised at right angles to that used formerly. For  $\sigma$  one now has  $\infty \geq \sigma \geq 4/3$ , for  $\rho \infty \geq \rho \geq 7/6$ , the relation between  $\sigma$  and  $\rho$  remaining unchanged. As Sir C. V. Raman mentioned in his letter that some new measurements of Venkateswaran had revealed that this phenomenon of "anomalous polarisation" could be best observed with thiophene, I repeated the experiment with this substance. The result was entirely negative, all Raman lines showing complete depolarisation, as was to be expected with an electric dipole radiation.

Sir C. V. Raman, to whom I communicated the result of this investigation, has answered by a letter, the relevant part of which is here published with his authorisation.

"Observations of depolarisation in excess of the  $6/7$ th permissible with incident natural light for an anisotropic electric dipole had been reported by several observers since 1928. The list includes Prof. Cabannes, Carrelli-Pringsheim-Rosen, Bhagavantam, West and Farnsworth, Parthasarathy, Venkateswaran, and others. I was impressed by this array of names, and hence was led to put forward the suggestion that a molecule may possibly scatter light also as a magnetic dipole or else as an electric quadrupole. Regarded purely as a theoretical proposition, I believe the idea to be sound. Spectroscopists have already shown that electric quadrupole radiation from atoms may be observed, and it seems not unlikely that several unexplained puzzles concerning the scattering of light may find an analogous solution.

"The remark in my note in NATURE of Nov. 7, 1931, reporting experimental confirmation of the idea by Venkateswaran was, however, premature. Subsequent experiments by Venkateswaran himself gave highly discrepant and puzzling results. The source of error appeared to be in the use of photographic

photometry, which in the case of very faint lines is liable, if sufficient care be not taken, to give misleading results. Bhagavantam has examined the matter systematically, and his conclusion is that all earlier reports of depolarisation of scattered light exceeding  $6/7$  for incident natural light are to be regarded as spurious and unjustified. No genuine exception to the  $6/7$ th rule has so far been established.

"As you are well aware, it follows from the electric dipole theory that when incident horizontally polarised light is used, all the scattered radiations must be completely depolarised. Your spectrograms with thiophene show this unmistakably to be the case, and hence must be regarded as disproving the existence of anomalous polarisation—at least in this particular case. I, however, still cherish the hope that quadrupole radiation from molecules may be detectable in specially favourable cases, and experiments with this object are being carried on here."

## Rapid Estimation of Water-Content in Undisturbed Soil and in Bales of Cotton

AN instantaneous method for estimating the moisture content of soil, at any particular spot below the surface of the ground, even approximately, should be very useful in plant physiology, irrigation, and in soil science generally. The high dielectric constant of water suggested to me that the variations in capacity of a 'leaky' condenser permanently buried in the soil should serve this purpose.

Alternating current from a valve oscillator is convenient to use for the purpose, but a capacity-bridge (such as is marketed by Messrs. Heilan, of Frankfurt) is impracticable, on account of power-losses to earth from the buried condenser. Resonance methods evade this earth effect (the circuit being symmetrical), and I have now worked out on this basis a technique which seems very satisfactory.

The buried condensers are conveniently made from glass web-tubing filled with mercury to give any desired capacity. Such double tubes can easily be made also in capillary form, and are then very sensitive: for example, a tube of  $1\frac{1}{2}$  mm. width externally has a capacity per centimetre of  $1.5 \mu\text{F}$  in air, which rises to a 'capacity' of  $6 \mu\text{F}$  per centimetre in water, with tubes of this size it is possible to examine localised details, such as the function of single roots.

The readings are but slightly affected by any variations of electrolytes above the level of minimum conductivity likely to be found in any soil. The 'capacity' indicated is predominately that of a zone only a millimetre or so in thickness around the tube, so that intimate contact with the soil is necessary, this is not a difficulty when the condenser is permanently buried in deep soil which never becomes air-dry. For other situations an artificial 'soil' of plaster can be cast round the tube, at the cost of making its responses sluggish.

The method can be used, with caution, for determining the concentration of mixtures of liquids which have different dielectric constants, such as alcohol and water: the web-tube is immersed in the liquid, and its gain in capacity subtracted from the variable condenser in parallel, until resonance is indicated by the grid-circuit galvanometer, which can all be done in a few seconds.

A further possible application is to 'works control'

of the moisture content of cotton bales as they issue from the power presses at Alexandria ready for export. At this moment their moisture-content is fairly homogeneous, their weight and volume are known, and the nine iron hoops securing the bale are of standardised dimensions and spacing. These hoops can thus be treated as condenser plates, which provide about 300  $\mu\text{F}$  total capacity on a bale weighing one-third of a ton and containing 8 per cent of moisture. About half of this is residual, the remainder being equally divided between the inter-hoop capacity in air, the effect of dry cellulose, and of the water therein. From this point additional moisture increases the readings rapidly (accompanied by blunting of the resonance curve due to conductivity), and the 'capacity' rises from about 300 at 8 per cent to 400 or more at 11 per cent. It should thus be possible to be sure that every bale lies between the limits of 8 per cent and 9 per cent permitted under the international agreement, and to effect this observation in about ten seconds only, which is even faster than the presses can produce the bales. The apparatus required is no bigger than an attaché-case.

In learning the technique necessary for effective use of these unconventional 'leaky' condensers, I have been helped very much by Mr. G. F. Briggs of Cambridge, by Mr. Moss of the Cambridge Instrument Co., Ltd., Mr. J. H. Cole of the Egyptian Survey, by my chemist colleagues here, Dr. W. H. Williamson and Mr. D. Grace, and by my son.

The first account and demonstration of the method was given before the Cairo Scientific Society on Feb. 28.

#### Behaviour of Bielschowsky-stained Neurofibrillæ between Crossed Nicols

ARTIFICIAL cultivation of tissues *in vitro* has little affected the field of investigation in organic neurology. The older histological methods are still irreplaceable, and of special value is that of Bielschowsky, which renders distinguishable the minute neurofibrillæ at all stages of development save possibly the earliest at which nervous conducting structures are present. Bielschowsky's method involves the staining of the fibrillæ probably with a complex compound of silver formed through the interaction of certain of its salts in solution with the chemical constituents left in the nerve after treatment with a series of 'fixative' reagents. At least, that is a possible explanation of the visible results viewed through the microscope. The colour of the fibrillæ varies from a dark to a very dark brown or black, and unfortunately non-nervous structures are also coloured a lighter brown or yellow, so that the actual identification of the fibrillæ is in practice inferred from their visible form and connexions as well as from their appearance more or less sharply contrasted with their immediate surroundings.

Any device which increases this natural contrast would be a technical gain facilitating detection of the minuter fibrillæ affected by the Bielschowsky reaction.

It is therefore of interest that in sections stained by Bielschowsky's method the neurofibrillæ are very distinctly visible in the 45° position relatively to the crossed nicol planes. Even the smallest filaments of the marginal layer of the embryonic central nervous system are revealed with great brilliance. Figs 1 and 2 reproduce the features of untouched photomicrographs of a lumbar nerve and *ramus communicans* in a 24 mm. human embryo (Zeiss 4 mm apo-

chromatic objective, substage polariser, and eyepiece analyser, Wratter 'A' filter, and panchromatic plates. For convenience, the polariser instead of the analyser was rotated, hence the faint cross lines in Fig 1 appear in an unconventional position. The actual planes of the nicols are indicated by white lines).

A few brief comments on this result may be of interest.

(1) The neurofibrillæ are more specifically distinguished in Fig 2 than in Fig 1, that is, when viewed between crossed nicols.

(2) Maximum illumination of the images occurs in four positions at right angles and there are correspondingly four 'positions of extinction' (crossed nicols).

FIG 1—Lumbar nerve and *ramus communicans* of a 24 mm human embryo. Nicols uncrossed  $\times 150$

FIG 2—Same preparation as Fig 1, with nicols crossed  $\times 150$

The exhibition of this phenomenon is regarded by petrologists as a demonstration of the presence of a crystalline substance. Prof. H. H. Read tells me that the question of an alternative inference does not arise when minerals are under consideration. Nevertheless, caution is necessary in dealing with animal matter. A liquid could scarcely have survived the process of preparation, and although elsewhere I have described the production of faint images by 'casts' of celloidin hardened in contact with striped muscle, such a surface phenomenon does not appear to be involved here.

(3) The apparent absence of continuity in the lines of Fig 2 (particularly in the larger nerve) is direct evidence of the 'extinction' phenomenon, since it is due to irregularities in the course of the fibrillæ. When the object is rotated, the images appear to flow along the fibrillæ. The anisotropic substance is

therefore evenly distributed, and the optical axes of the particles have a common or parallel direction relatively to the axis of each fibril

(4) Since the images with crossed nicols are single narrow bands, uniformly illuminated, it seems that the Bielschowsky method is not an 'incrustation method'. The word 'impregnation', too, is ambiguous

(5) The reaction depends upon the specific constitution of the nerve, physical or chemical, so far as a section of animal tissue is concerned, since the optical properties are not displayed by non-nervous stained structures present, for example, the nuclei of erythrocytes, surface deposits, or mesodermal trabeculae, although this generalisation is subject to qualification (see 10 below)

(6) Living nerve is anisotropic

(7) Arising from (6), the arrangement of the anisotropic substance in Bielschowsky preparations may be due to the constitution of the nerve itself, or it may be due to the formation, in combination with the nerve, of an anisotropic substance, or it may be due to tension in the neurofibril

(8) Section of other embryonic material at a comparable stage stained with hæmatoxylin and eosin, Mallory's *saure fuchsin*, etc., and Haidenhain's hæmatoxylin do not exhibit the phenomenon. Preparations of adult mammalian tissues stained intra-vitally with methylene blue show it, but only for very short stretches of the nerve where, apparently, it is not well stained. This observation is at present confined to myelinated fibres, and the anisotropic parts appear to be localised near the nodes of Ranvier. Weigert preparations of the adult human central nervous system give a negative reaction for the nerves but a positive reaction for the adventitia of blood-vessels

(9) Striated muscle stained by Bielschowsky's method exhibits a 'sheen' when viewed between crossed nicols. I have not been able to determine whether the source of this 'sheen' is localised in the anisotropic discs as it is in unstained fibres

(10) In some preparations of a primitive vertebrate, the phenomenon is exhibited by certain elements in relation to the trabeculae of the notochord. This limitation upon (5) is itself interesting and will be the subject of further observation, for nerves have been recorded as entering the notochord<sup>1</sup>. Further, Bielschowsky material from the same subject as the Weigert material mentioned in (8) gives a strongly positive reaction for nerves and a *weakly positive* reaction for the adventitia. The peculiarities of the connective tissue in material from adults may thus limit the usefulness of these observations to young tissues, but this is uncertain

### Nature of the Ionic Conductivity of Glass

It has been found experimentally,<sup>1</sup> that the equivalent conductivity of glasses of the system  $B_2O_3 + Na_2O$  increases very sharply (a million-fold) with the concentration of sodium in the glass. This increase begins at a definite concentration, about 3.5 per cent  $Na_2O$ . In order to elucidate the nature of these facts, the velocity of solution of the glasses was measured. These experiments have shown that with this system the curve of the rate of solution has a maximum and, further, a sharp fall in a certain region of concentration of  $Na_2O$  corresponding to the very beginning of the increase of equivalent conductivity (Fig. 1). Analysis of the quantitative data of the rate of solu-

tion indicates that orientation of polar molecules of borates of sodium in this region occurs.<sup>2</sup> According to Tamman's well-known data, there exist in the  $B_2O_3$  glass certain positions unoccupied by molecules (free positions).<sup>3</sup> It is easy to conclude that in the region of the increase of the equivalent conductivity, the increase of orientation of the molecules leads to their more compact packing, and this, in its turn, leads to the disappearance of free positions (positions unoccupied by molecules). In the region of small concentrations of  $Na_2O$ , the molecules of the borates of sodium are separated from each other and practically do not interact. Elementary considerations, which we here omit, make it possible to assume that the layers of the  $B_2O_3$  molecules disappear among the polar molecules of the borates of sodium just in the region where equivalent conductivity begins to increase. It is therefore natural to expect the

FIG. 1—*a* Equivalent conductivity at 250° C. of a borax glass, *b* velocity of solution at 100° C.

appearance in this region of a tendency to orientation among the molecules of borates, and at the same time a decrease of the energy of their dissociation ( $Na_2B_4O_{13} \rightleftharpoons Na + NaB_4O_{13}$ ) as a result of their interaction. Owing to this, we obtain a great increase of conductivity, caused, as we know, by the sodium ions

From what has been said, a subdivision follows of glasses

(a) Glasses with low sodium content. Owing to free (unused) positions, all dissociated ions have translational motion. The dissociation energy of borates does not depend on the concentration of sodium, owing to the absence of interaction between the polar molecules of borates separated from each other by the  $B_2O_3$  molecules. These conclusions agree with the experimental fact that the concentration of sodium does not influence the equivalent conductivity.<sup>1</sup>

(b) Glasses with high sodium content. Owing to the gradual disappearance of free positions, the channel-like displacement<sup>4</sup> of the ions of sodium increases, consequently, the effective velocity of the translational motion of the ions decreases. Experimentally it is manifested in the considerable decrease of

the value  $B - \ln c$  in the expression of the logarithm of equivalent conductivity

$$\ln \frac{k}{c} = -\frac{A}{T} + (B - \ln c)$$

(in which  $T$  is temperature,  $c$  sodium concentration,  $A$  and  $B$  constants) Nevertheless, the equivalent conductivity of glass greatly increases owing to the decrease of energy of dissociation of borates as a result of the interaction of their molecules Experimentally

it is shown in the fall of the coefficient  $A \approx \frac{E}{4}^{1,5}$

It is found that the dissociation energy  $E$  falls with the increase of molecular concentration of the polar molecules of borates  $m$  (per  $\text{cm}^3$  of glass) according to the equation

$$E = \frac{3.6}{\sqrt{m}} \text{ cal}$$

The transition from the vitreous to the crystalline state is followed by the disappearance of the free positions<sup>3</sup> The fall of conductivity to be expected in this case is shown experimentally to take place in the system  $\text{Na}_2\text{O} + \text{SiO}_2$ <sup>6</sup>

It seems that the maximum of the rate of solution corresponds to the intermediate region of concentration in which the  $\text{B}_2\text{O}_3$  monomolecular layers disappear, the molecules of borates, which were formerly separated from each other, are now drawn together and begin to interact, the van der Waals' cohesion forces between the  $\text{B}_2\text{O}_3$  molecules in glass are replaced by forces acting among the polar molecules of sodium borates

#### Application of the Electrometer Triode to the Measurement of High Resistance

In some experiments made by us on the application of the electrometer triode to the measurement of the ionisation produced by radioactive substance and X-rays, alcohol xylol resistances of the order  $10^3$ - $10^6$  megohms have been employed A method of measuring such resistances has been devised, in which use is made of the very high grid-filament resistance of the triode The arrangement is indicated in Fig 1  $R_1$  is a known resistance,  $R_2$  is the resistance to be determined With the potentiometer short-circuited and the key  $K$  open, the normal anode current is first balanced by variation of the resistance  $Z$  in the short-circuit  $GZ$ , so that the galvanometer indicates zero The key  $K$  is now closed, and the current in the circuit  $ER_1R_2$  alters the voltage of the grid by an amount equal to the voltage drop across  $R_1$  The anode current is thereby altered, and the galvanometer is deflected The grid is now restored to its original potential, by applying to it a potential by means of the potentiometer  $P$ , the reading of the potentiometer  $e$  being a measure of the voltage across  $R_1$  Obviously then

$$R_2 = R_1(E - e)/e$$

Resistances up to  $10^6$  megohms have been measured in this manner, the procedure being to construct a series of alcohol-xylol resistances of the order  $10^2$ ,  $10^3$ ,  $10^4$ , and  $10^5$  megohms The lowest of these is first compared with a standard resistance of 10

megohms This is then used as a standard to measure the  $10^3$  megohms, the process being repeated for the higher resistance

$E$  is usually a two-volt battery, and for accuracy the ratio of  $R_2/R_1$  should not be much less than 10<sup>1</sup> The valve employed in these measurements is supplied by Philips Lamps, Ltd, and its chief characteristic, which makes it so suitable for such measurements, is that the grid current, when the grid bias is

FIG 1

- 2 volts, is less than  $10^{-14}$  amp The method cannot be employed for resistances above  $10^7$  megohm, as resistances of a higher order are comparable with the grid filament resistance of the valve

The potentiometer employed is by the Cambridge Instrument Co, Ltd, and a comparatively insensitive galvanometer (1 division per microamp) is sufficient

Further details of the method will be published later, in connexion with the work on ionisation measurements which are in progress

#### The Revival of Scholasticism

I It is difficult to see just what is the meaning attached to 'direct contact' in the statement that "we have no means of getting into direct contact with them [physical objects]" ("The Decline of Determinism", NATURE, Feb 13, p 235) For, the fact that the sense-organs merely reflect objects is not a modern discovery it was the basis of Francis Bacon's inductive philosophy "Our method is continually to dwell among things soberly, without abstracting or setting the understanding farther from them than makes their images meet" "For however men may amuse themselves, and admire or almost adore the mind, it is certain that, like an irregular glass, it alters the rays of things" "The capital precept for the whole conduct is this, that the eye of the mind be never taken off from things themselves, but receive their images truly as they are." "The mind is like a glass, capable of the image of the universe as the eye to receive the light" (Preliminaries, "De Augmentis Scientiarum")

In the "Anugitā Upanishad", one of the earliest known philosophical writings, it is repeatedly stated that the senses are conscious only of the qualities of 'objects', which are themselves merely appearances—*Māyā*, in effect, merely condensations or accumula-

tions of energy. Any 'contact' with these accumulations can be, of course, but our consciousness of an electromagnetic 'contact' or interaction. This 'sensation' of an 'image', a 'sound', etc., is immediate. Inferences are subsequent and are formed by another aspect of consciousness—the *rational mind*, an extreme development of the function which operates in the higher animals *immediately as instinctive inferences*. 'Time' is, therefore, a synonym for deliberation and ratiocination about appearances. It deludes speculative thinkers, who, as Bacon pointed out, confuse metaphysics with physics, 'final causes' with 'physical motions'. They expect to find the principle of cause in the chimeras of the mind.

II The *inferences* with which the external world is said to be populated (p. 236) are the progeny of human reasoning, which erroneously presumes that 'time' is predicative and causal: they are not born of judgment by induction, whereby "we both find and judge by the same operation of the mind, almost in the same manner as by the sense", that is, when the understanding reflects the inner 'forms' of things. Bacon should be re-read in the light of our modern knowledge of electromagnetic induction. 'Cause' is in the nature of things, not in 'time' or in ratiocination. Things are so, and could not be otherwise, given a certain *combination* of 'relations' and 'motions'. That which is given is isolation or tension, which is independent of 'time'. Experimental science has been built up on a progressive knowledge of the principle of isolation, and this has been obtained by the inductive use of the mind, in Bacon's sense. "A true and legitimate union between the experimental and rational faculty, the undue separation thereof has caused the greatest disturbances in the family of mankind"—theological disputes and religious persecutions.

III It is surely not correct to state (p. 233) that 'determinism' has been the attitude of science for more than two hundred years. The word itself shows its scholastic origin. Its crude connotation was foisted on science in the nineteenth century—not by *experimental workers*. Father Félix, the famous preacher at Notre Dame de Paris in the 'fifties, foresaw the inevitable reaction from 'determinism' and 'predicted' that mystery would be the fatality of science. To-day the clerical party in the popular press are boasting that "science has lost its old arrogance", that its labours have been in vain, and that man must resign himself to uncertainty with regard to knowledge. 'Determinism' and 'indeterminism' are alike speculative inferences of Neo-scholasticism, which is flourishing to-day in England and on the Continent because inductive philosophy has provided it with a vast amount of data on which to speculate. There is a point in the cycle of every civilisation when sophistical thinking balks the work of experimental science, and the civilisation thereafter declines.

IV The labours of the great experimenters demonstrate that, as a creative thinker, man is superior to physical Nature. He can insulate his mind, shut out the rays reflected by the appearance of things, stop the activity of the 'natural reason' temporarily, and so induce an energy in the brain, of an order different from the energies of physical propagation and reproduction, which effects transformations, whether indirectly in the laboratory or directly in the physiological 'habits' of his own organism (p. 240), and alters tendencies to normal or natural reactions. Man creates civilisations and their arts, reshapes his environments, and can remould his thoughts, if he will. Has a brain of this generative power been found elsewhere in Nature? Hence, it seems "incredible what a number of idols have been introduced into

philosophy by the reduction of natural operations to a correspondence with human actions, that is, by imagining Nature acts as man does, which is not much better than the heresy of the anthropomorphites that sprung up in the cells and solitudes of ignorant monks" ("De Aug. Scient.", XIV.)

W W L

### Determinism

IN discussions which have taken place recently in the columns of NATURE, and elsewhere, on the subject of determinism, various aspects of the problem are omitted which appear to me to be important. In the first place, both determinism and indeterminism are subjective phenomena, dependent on mind, and subject to its limitations, including fallibility. Secondly, they are eternally associated in mind, and become meaningless in isolation. A universe ruled entirely by determinism is to me as unthinkable as one subject to pure chance. The difficulty is with our human minds to attempt to adjust ourselves to a world which appears to be partly determined and partly fortuitous.

In the inorganic, and microscopic, world, scientific research steadily eliminates the element of chance, as experimental error diminishes. Astronomical phenomena can now be calculated with very fine precision, and earthquakes are no longer considered to be entirely capricious. It matters little whether uncertainty still reigns in atomic physics, since even the realisation of this has been arrived at by methods which, in being scientific, rest on an implicit faith in causality. All we can say is that at present we do not *know* exactly how an electron behaves. By analogy we may at least expect that the path of an electron is as rigidly determined as that of the earth, or the moon, we merely know less about it. Similarly, although the shaking of a box of dice may be a purely physical process, the results will appear to us to be governed by chance, simply because we cannot calculate and measure all the forces involved. Here chance emerges on one side as a measure of the limitations of human mind, and on the other, of the complexity of the universe.

In the organic world the problem becomes greater, while remaining essentially the same. A living thing has a biological urge which we recognise as purpose, and which determines how it will behave. This presupposes a universe sufficiently reliable to admit of adaptations, for adaptation in itself implies necessity, but since it can never be perfect, a margin is left over for chance, and for evolution, while within one generation chance determines food supply, survival, reproduction, and dispersal. In absolutely identical situations we may well expect identical twins to react in exactly the same way, but identical twins are comparatively rare, and identical situations, in our knowledge, are rarer still. There is therefore scope for free will, in so far as on one side the universe is apparently governed by necessity, and on the other is capricious enough for individual decisions to be made.

In naive experience we human beings are conscious of both determinism and chance. To us the slavery of the ant appears repulsive, and while we try to eliminate the element of chance from economic life, the logical outcome of our efforts would terrify us. Some equilibrium between determinism and chance appears to be an essential condition for a healthy life. Such an equilibrium lies at the root of many human activities, as in conventions, fashions, morals, adventure, and romance. It supplies a basis for the assessment of character. It runs as a thread through all art, which on one side is limited by reality and style, and on the other admits of individual imaginative

treatment It appears in betting, and it is the basis of all games The degree of capriciousness which can be tolerated varies for each individual, but it never vanishes

### Physiological Specialisation of *Hemileia vastatrix* B and Br

In the course of some recent work on the behaviour of a number of hybrids and selections of *Coffea arabica* Linn, collected at the Mysore Government Coffee Experiment Station, towards infection by *Hemileia vastatrix* B and Br, indications of the existence of physiological specialisation in this rust fungus have been obtained

It had previously been found possible to carry out inoculation experiments on detached leaves in the laboratory, and to keep such leaves healthy for at least six weeks The method was applied to testing a number of resistant and partly resistant selections Among these, one selection, *S* 5/30, was found to be completely resistant to spore collections made from the Coorg variety of *Coffea arabica*, though it showed

Identical results have been obtained in a number of similar experiments There are indications of very minute chlorotic flecks in the case of Coorg spore infections on *S* 5/30 leaves, and the histology of these flecks is shortly to be investigated The infections caused by the two spore collections on the Coorg leaves and the *S* 5/30 spore collection on the *S* 5/30 leaves are morphologically indistinguishable

Up to date, only one plant exhibiting this difference in behaviour to different spore collections has been found Work is in progress involving the study of plants of the same origin as *S* 5/30 and other plants showing variations in behaviour to *Hemileia vastatrix* A full account will be published when results are available

I am indebted to Mr M J Narasimhan, mycologist, Department of Agriculture, Mysore State, for the photographs of infected leaves

### Microscopic Measurements

In elementary biological classes the measurement of microscopic objects is useful for training in accurate observation and for the intelligent use of the various parts of the microscope In this connexion it may be pointed out that the estimation of the vertical distance between objects in microscopic preparations helps greatly in the realisation of solid forms and of the information which may be obtained from superimposed optical sections The estimation can be made very simply by the use of a microslip carrying on one side a short line of transparent red, and on the other a similar line of green, glass ink The lines cross each other and form an 'X' when one looks vertically through the slip. From the thickness of the slide at X, ascertained with a coverglass-micrometer, and the number of revolutions of the milled head of the fine adjustment of the microscope, which are required to pass from the level of the focus of the red to that of the green line, the pitch of the screw and the value of the movements of the fine adjustment are obtained

Despite errors due to accommodation and refraction the use of the fine adjustment calibrated in this way is very advantageous, and, when combined with micrometric observations in a horizontal plane, conveys a sense of solidity which can scarcely be obtained so simply by any other method By way of example, the vertical diameter of a filament of *Spirogyra portucalis* was estimated by this method as 0.021 mm, while its horizontal diameter, found by the 'ghost micrometer', was 0.0198 mm

### Catalysis in an Inert Solvent

As Dr Traill is now in Australia, I may direct attention to the fact that calculations of a similar character to those given by Dr Moelwyn-Hughes in NATURE of Feb 27, p 316, had already been made by him These were published in the February number of the *Philosophical Magazine* under the title "Kinetics of a Catalysed Isomeric Change in Solution", whilst Dr Moelwyn-Hughes's letter was in the press

## Research Items

**Troy**—Archæological and geographical problems relating to the site of Troy and its identification with Hissarlık are discussed by Miss Winifred Lamb in *Antiquity* for March in the light of her excavations at Thermi in the Island of Lesbos. Doubts, which had long been dormant, have been raised recently by the contention that there was no room for the Achæan camp and the actions described in the *Iliad* on the land between Hissarlık and the Hellespont. A number of treatises have maintained in consequence that Hissarlık is not Troy, and that Troy was not situated on the Hellespont. An alternative site at Besika on the west coast has been suggested, but is untenable, while the view that Hissarlık was a burial ground of the Achæans is not in accordance with archæological fact. If another Troy is to be found, it must be by excavation of some of the still unexplored mounds of the Troad. At present the position of Hissarlık can be tested only by comparison with other settlements of the same culture. The excavations at Thermi for the first time have afforded architectural material which can be placed side by side with that of Troy. Five towns, one above another, have been uncovered, giving the whole plan of the upper town with about three-quarters of each of the others. The period after Troy I when Hissarlık was deserted was for Thermi III a period of growth and activity, and Thermi also reflects the prosperity in Anatolia which was heralded by the foundation of Troy II on an unprecedented scale. Before the fall of Troy II, destroyed possibly by the Hittite, the Thermiotes seem to have anticipated danger, for they abandoned the site.

**Thorn-lined Traps**—An interesting question of distribution is raised by Mr Henry Balfour in *Man* for February in describing certain thorn-lined traps now in the Pitt-Rivers Museum, Oxford. A note on specimens of these traps which appeared in *Man* in 1925 has elicited information of examples from different areas and in use by various peoples, showing practically a continuous dispersal range from the area north of the Brahmaputra to Melanesia. The traps are clearly closely related to one another and have a common origin. An example is now known from a new and unexpected locality. It was collected by Dr E. Evans-Pritchard among the Azande of the Welle District in eastern Sudan. This trap is a long narrow tube of open basket-work, consisting of eight strips of split cane fastened together at one end and running in a nearly parallel, but slightly diverging, series to the full length of the trap. The strips are woven to form a rigid, slightly tapering basket in which three thorn-bearing twigs are fastened, so that a small animal, such as a rat, is afforded easy ingress, but cannot back out. It resembles very closely a type found among the Konyak Nagas, which is also used for catching rats. The occurrence of this type of trap after so wide a gap in distribution raises an interesting question as to whether it is to be referred to a common prototype or is to be regarded as a case of independent origin. A tubular form of trap, but differing in action, is widely dispersed in tropical Africa.

**Growth of Wool in Australian Merino Sheep**—By the periodic measurement of the mean length of adjacent locks or staples at fixed points on the shoulders of the merino sheep, K. M. Fraser has investigated the growth of the fleece of merinos grazed on 'natural' pastures throughout the year (*J. Coun. Sci. Indust.*

*Res.*, Australia, 4, 204, 1931). It is to be noted that the elongation of the staple does not necessarily correspond to the average rate of growth of all the fibres in the staple, but it is on staple form that breeder, buyer, and wool expert base their judgments. Fraser found that the body-weight of the sheep themselves showed very considerable fluctuations, associated with the alternation of periods of drought and heavy rainfall during the year and consequent shortage and luxuriance of pasture. But in spite of this, the rate of growth of the staples showed uniform progress throughout the year, the actual increase from the first measurement of 30.26 mm in November to the corresponding time in the following year being 114.20 mm (3.3 in). It is probable that the principal effect of the seasonal drop in weight of Australian sheep in autumn, when the nutritional value of the natural pastures falls away, is reflected in the thickness of the wool fibre instead of in the staple length.

**Habit and Physiology of *Calanus***—The Annual Report (1930-31) of the Scottish Marine Biological Association shows that research is flourishing at the Millport Marine Station. Mr A. P. Orr and Miss S. M. Marshall have devoted themselves mainly to the study of *Calanus finmarchicus*. Samples of about a hundred individuals were taken from the tow-nettings at least once a month throughout the year, the proportions of males, females, and young stages determined and a certain amount measured. The main breeding period is early spring but reproduction goes on sporadically throughout the summer. The largest specimens are to be found in April. During autumn and winter, when *Calanus* was very scarce elsewhere, there were always large numbers to be found in the deep waters of Loch Fyne, mainly immature. Experiments have been made on the rate of metabolism, as measured by the oxygen consumption, of males, females, and stage v (the stage immediately preceding maturity) under different temperatures, oxygen content, and hydrogen ion concentration. It is found that lower oxygen concentration can be tolerated at lower temperatures. The lowest values they can tolerate are met with only occasionally in the sea, and *Calanus* is apparently insensitive to the changes in the hydrogen ion concentration which are likely to be met with under natural conditions in the sea. Males and females behave similarly so far as they have been compared, but immature *Calanus*, in spite of their greater activity, have a lower oxygen consumption. Research on the digestive enzymes of *Calanus* gives much promise for future work. Enzymes have been obtained which will split cane sugar, starch, and glycogen to give reducing sugars, and others which liquefy gelatine and attack fibrin to a slight extent.

**A Fungus Disease of Lavender**—Price-competition and the 'shab' disease have combined to send lavender out of cultivation in England. It only remains for growers to make a fresh start, in view of the recent imposition of duty on foreign perfumes and the fact that the 'shab' disease is now known to be caused by a fungus—*Phoma Lavandulæ* ("The 'Shab' Disease of Lavender", by C. R. Metcalfe, *Trans. Brit. Mycol. Soc.*, vol. 16, parts 2 and 3, pp. 149-176, Dec. 1931). Mr Metcalfe has shown this conclusively by inoculation experiments, but has also demonstrated that certain climatic and edaphic factors may produce similar symptoms. Methods of control based on plant hygiene have proved successful in

several instances. The main trouble, however, lies in the fact that a plant may be infected for a considerable time before it shows symptoms. This has resulted in the spread of the disease under the older conditions of propagation, such as the splitting of whole plants to form cuttings. A method of taking small cuttings from soft, green woody shoots has given good results in controlling the disease. *Lavandula dentata* and the dwarf French variety of *L. vera* are reported to be immune from the disease, though non-fragrant, and offer good possibilities for the production of perfume-bearing immune varieties.

**Bermuda during the Ice Age.**—Mr Sayles has now summarised his study of the Bermuda Islands during the last eight years ("Bermuda during the Ice Age", *Am Acad Arts Sci*, vol 66, No 11). The Bermuda volcanoes, erupted during the Tertiary or earlier, were reduced by the end of the Tertiary to submarine platforms. With the coming of the Pleistocene glaciation, water was subtracted from the oceans to cause a fall of the strand line to as much as 260 ft below present sea-level. While the ice-cap grew large, parts of the Bermuda banks, covered by marine deposits and unprotected by vegetation, were exposed to the sweep of the winds, and the dried sands were piled up into great dunes. These dunes were preserved owing to the very quick cementation that takes place when this eolian shell sand is exposed to the atmosphere. Their formation was favoured by the inevitably harder and more stormy conditions of the ice age in this latitude. The sea rose at the close of each glacial stage, the bases of the dunes were buried beneath the waves, the winds became less violent, and a permanent flora anchored the dunes. Soil accumulated, but with the advent of new glacial stages conditions became again favourable to the formation of dunes, which covered up the earlier soil layers. The geology and palæontology of these interglacial soils are carefully studied, and enable the author to suggest in detail the history of the formation of these islands in the Pleistocene. Lastly, a twelve-foot drop in sea-level is recorded by an emerged bench, cut probably only a few thousand years ago. Bermuda has long been known not to be an atoll, its corals being only the thinnest of veneers. Its basin, about sixty feet deep, perhaps owes its existence to the protection of the central parts of the former land by the dunes which lie round it to the south and east. We judge that the Challenger and Plantagenet Banks to the south of Bermuda, covered by about thirty fathoms, were probably too small for the permanent formation of dunes.

**Passage of Ionising Particles Through Matter.**—The question of the relation between the energy of a charged particle and the rate at which it can produce ions in a gas has become one of the main and most unsatisfactory problems connected with ionisation. Following upon earlier theories of the effect, due to Bohr and others, a new attempt at the analysis of what occurs was made two years ago by Bethe, on the basis of the wave mechanics. The *Proceedings of the Royal Society* for February contains two papers, by E J Williams and by P M S Blackett, the main theme of which is the comparison of Bethe's theory with experiment. The general conclusion seems to be that Bethe's theory is an advance on earlier work, but that it is still not a completely adequate account of what occurs. Various ways of reconciling the divergence between theory and experiment are considered, but special interest is perhaps attached to the point made in Williams's paper that there is ambiguity in what have generally been considered straightforward ionisation experiments. This arises

in two ways, from an electrode effect, and from an effect of impurity in the gas. The former is that, as has now been established in many experiments, there is an emission of electrons in most circumstances when positive ions are neutralised at a metal surface, this would increase the ionisation current recorded over that due to the primary production of ions in the gas. The latter is that excited atoms may ionise impurities in the gas, and again produce an additional source of current to the collecting electrodes. It is not clear if these will account completely for the discrepancy between theory and experiment, and there is in fact some indication that this will not be the case, but it has been shown that there is need for reconsideration and improvement of technique in this type of work.

**Testing Broadcast Receivers.**—The testing of broadcast receivers is much more difficult than testing other electrical appliances. It is possible to get definite results under definite conditions, but to use these results to compare the relative merits of receivers under widely different conditions is practically impossible. The paper, therefore, read on March 2 to the Institution of Electrical Engineers by H A Thomas on the methods of testing radio receivers at the National Physical Laboratory should prove useful to both manufacturers and users of broadcast apparatus. A suggested specification of the requisite tests is given, together with the experimental results obtained. This specification is examined as to how far it is applicable to the relative comparison of widely varying types of receiver, the number of necessary tests being reduced to a minimum, and a new method of expressing the results of the tests by a 'figure of merit' is explained. It is possible with modern receivers to obtain a very large range of sensitivity, but this test by itself is not of great importance. The author suggests that a definite value of the sensitivity be fixed and the other properties of the receiver determined at this rated value. Most receivers are required to operate under known local conditions. The field strength is known when the receiver operates in a known broadcast service area. So also, the amount of interference from other radio stations, the hum from the supply mains, the noise from tramways, etc., are approximately known. The receiver should therefore be tested as nearly as possible under the known conditions of working. The field is divided into three service areas, A, B, and C, the field strength of A exceeding 10 millivolts per metre and that of C 2.5 millivolts per metre. As the output of receivers differs so widely, they are divided into five classes according to their output. A 'B3' receiver, for example, is one which gives a medium output—that is, one lying between 500 and 1000 milliwatts when a field strength of 5 millivolts per metre is applied to the standard aerial.

**Induced Molecular Asymmetry.**—Prof Richard Kuhn, of Heidelberg, has observed (*Ber deutsch chem Gesell* Jan 1932) some optical effects in solution which he suggests may help to throw some light upon the biological formation of optically active compounds from inactive substances. Thus the salts which *p p'*-dimetrodiphenic acid forms with quinine and cinchonine are very strongly dextrorotatory, the value for the specific rotation for sodium light of the quinine salt being about +700°, whereas the salts which these bases form with *m*-nitrobenzoic and phthalic acids exhibit merely normal levorotatory values. The strong dextrorotations are attributed to the development of an asymmetric configuration of the diphenyl nucleus similar to that described by Christie

and Kenner In the present case, however, the asymmetry and consequently the activity disappear as soon as the optically active base is eliminated, since there is no sterically hindering substituent present in the ortho position to interfere with the free rotation of the two aromatic nuclei about their common linkage The author suggests the term 'asymmetric rearrangement (*Umlagerung*) of the first kind' to distinguish it from that 'of the second kind', which is permanent and is the usual type involved in the usual resolution of racemic compounds If the explanation is correct, this would appear to be a remarkable case of 'induced asymmetry', first described by Lowry and E E Walker (*NATURE*, April 19, 1924, p. 565) in connexion with semi-polar double bonds.

**Magnetism of Bivalent Copper and Silver Compounds**—For atoms of the first transition period (scandium to copper) the magnetic moment in Bohr magnetons is  $\mu_a = \sqrt{4s(s+1)}$  or  $\mu_B = \sqrt{4s(s+1)} + l(l+1)$ , where  $s$  is the total spin moment of the electrons in the sub-group and  $l$  the orbital magnetic moment Most simple salts of elements in this period give values corresponding with  $\mu_a$  Univalent copper and silver have a complete sub-group of 10 electrons, in a  $3s$  level for copper and a  $4s$  level for silver They are therefore diamagnetic Bivalent copper and silver

ions have nine electrons in this sub-group and should be paramagnetic With  $s = \frac{1}{2}$  and  $l = 0, 1$ , or  $2$ , the values of the moments are  $\mu_a = 1.73$  and  $\mu_B = 1.73, 2.24$ , or  $3.00$  It has already been shown (*NATURE*, 128, p. 31, 1931) that the bivalent silver in *tris-aa'*-dipyridyl argentic chlorate is paramagnetic, and Sugden (*J Chem Soc*, Jan) has now examined a number of other co-ordination compounds of bivalent silver and also cuprous and cupric compounds Bivalent silver is known only in the form of co-ordination compounds of its salts with substances such as pyridine and dipyridyl He finds that both copper and silver in the univalent condition have zero magnetic moment, whilst the bivalent atoms of both elements exhibit moments of 1.72-2.16 Bohr units, in fair agreement with the value predicted for one unbalanced electron In the same issue of the *Journal* this author also describes the measurement of the moment of a paramagnetic organic compound which contains an odd electron, prepared by Kenyon and Banfield in 1926 This gave a moment of 1.68, close to the value 1.73 for one unpaired electron Excluding substances which contain transition elements with incomplete inner groups, chlorine dioxide, nitric oxide, and nitrogen peroxide have previously been examined The first two give approximately the values expected for one unpaired electron, but the nitrogen dioxide is somewhat anomalous

### Astronomical Topics

**Astronomical Notes for April**—Venus is resplendent in the evening sky It is at its greatest elongation,  $46^\circ$  east of the sun, on April 19, being then half-illuminated The illuminated portion of the disc diminishes during April from 0.60 to 0.44, the stellar magnitude rises from  $-3.8$  to  $-4.1$  Jupiter is still observable for more than half the night, but its diameter is diminishing On the evening of April 19 only two satellites are visible after 7.25 p.m., III being eclipsed and II occulted

A star of mag. 6.4 is occulted by the moon on April 9 at 10<sup>h</sup> 14<sup>m</sup> p.m. The moon is barely 4 days old, and the earthshine should be conspicuous, this makes it easier to note the approach of the moon's limb to the star

Two periodic comets, Grigg-Skjellerup and Neujmin (2), should be telescopically observable, ephemerides are given in the British Astronomical Association's Handbook for 1932

Only two minima of Algol occur at convenient hours, on April 2 at 8<sup>h</sup> 12<sup>m</sup> p.m., and on April 22 at 9<sup>h</sup> 54<sup>m</sup> p.m.

Summer Time begins on April 17, 1<sup>h</sup> must be added to the times given above, to express them in Summer Time Note, however, that Summer Time should not be used in astronomical records

**An Ancient Conjunction of the Moon and Venus**—Dr P. V. Neugebauer has published a note (*Astr. Nach.*, 5847) on a cuneiform record which describes an observation made at Babylon on the morning of the 25th of Sivan in the 5th year of Darius Ochus ( $-418$  June 19) He uses it to test various values of the mean motion and secular acceleration of the bodies concerned The record uses the word 'night' and states that Venus coincided with the moon's southern horn It may therefore be assumed that the conjunction occurred some time before sunrise, which fixes the time within rather narrow limits The author concludes that Dr Cowell's large value of  $4''$  per century for the sun's acceleration is ruled out The use of Brown's Tables for the moon, and those of Newcomb for the sun and Venus, brings the

time of conjunction into daylight Schoch's values for the secular accelerations give a satisfactory representation of the observation, but it is also possible to satisfy it with values considerably different The observation is, however, sufficiently definite to receive some weight in a discussion of ancient records

**Interesting Object with Rapid Motion**—M. Delporte, assistant at the Royal Observatory of Belgium, Uccle, discovered an object of the ninth magnitude on March 12 that was almost in opposition to the sun and yet was advancing more than  $1\frac{1}{2}^\circ$  daily, and moving north at about the same rate Its aspect was stellar, but its motion indicates cometary nature Though approaching both sun and earth, it faded quickly, Dr Steavenson finding the magnitude 13.2 early on March 18

An I.A.U. telegram gives the following parabolic orbit computed by Dr Bengt Stromgren

|          |                        |

|------------------------------|---------------------------------------------------------|----------------|
| Ephemeris for 0 <sup>h</sup> | March 26 13 <sup>h</sup> 55 <sup>m</sup> 0 <sup>s</sup> | $25^\circ 45'$ |
|                              | March 30 14 38 56                                       | 31 42          |

Almost identical elements were deduced by the Rev. M. Davidson Dr A. C. D. Crommelin notes that the orbit is very similar to that of the comet Tuttle-Giacobini, 1858 III and 1907 III If it is identical with that comet,  $T$  is about April 11, period about 6.2 years,  $q$  about 1.11, the remaining elements being nearly the same as Dr Stromgren's The identity of the above two comets was not immediately recognised It was first suggested by Prof. W. H. Pickering, and is highly probable, whether the present object is the same body or not If it is the same, it has lost most of its gaseous envelopes since 1907, but there must have been some kind of outburst about March 12 to explain its temporary brightness then

## Quantitative Methods in Vitamin Assays

THE variability in the responses of a group of animals to the administration of the same substance usually necessitates taking, as criterion of response, the average for the group. In many instances, even with the use of a large number of animals, the average response shows significant variations when the administration of the same dose is repeated on different occasions. If the assay is to have any quantitative value, it is essential to use a standard of reference, with which the substance under test can be directly compared. Thus the individual variations within the group are controlled by the use of a sufficient number of animals, such that each time the group selected is truly representative of the population available for test, whilst the variations in sensitiveness from day to day are controlled by the use of the standard of reference.

These principles have been applied, in certain recent investigations, to the improvement of the animal tests for some of the vitamins. A further complicating factor here is the difficulty, frequently encountered, of estimating the degree of response in other tests, death or convulsions, for example, are definite end points, and it is often possible to measure accurately the amount of a drug which will just arrest the heart. In vitamin assays, the growth rate is often a valuable criterion, susceptible to a fairly wide range of quantitative expression, but it suffers from the disadvantage of being affected by a variety of factors other than the one under test. In other cases, it may not be possible to give any numerical expression, other than a purely arbitrary one, to the degree of response: thus, in vitamin D assays, it is usually possible to say whether a degree of calcification induced by its administration is greater or less than that observed in the bones of other animals, but not how much greater or how much less.

A recent report from the National Institute for Medical Research describes a method for overcoming these difficulties in vitamin D tests and for obtaining results accurate to within a few per cent.<sup>1</sup> The general management of the animals was that usual in such tests: young rats were fed on a restricted diet until 45–50 gm in weight and 3–4 weeks old, and then given Steenbock and Black's rachitogenic diet for four weeks. At the end of the first two weeks, the animals were anaesthetised with ethyl chloride and their right knee joints radiographed; for the second two weeks they were given daily doses of vitamin D in oil by pipette. They were then killed and the right knee joints again radiographed. The first radiographic examination enabled the observers to reject animals showing imperfect rickets, since it was found that the degree of healing obtained in the subsequent two weeks did not give the same picture as that shown by animals with severe rickets, and also that the variations between litter mates were greater when the rickets was milder. Too severe a degree of rickets also increased the variability of the response to the vitamin. The doses of the latter were always in the ratio of 2:1, in each litter, equal numbers of animals were placed on the standard solution and on the solution under test. The odd animal in uneven litters was kept as a negative control. The standard solution used was about thirty per cent stronger than that now issued by the Institute for general use.

For their assays, the authors constructed a scale of healing: photographs were selected showing just perceptible differences from each other and arranged

in order from no healing up to complete healing. Twelve such steps were distinguishable, although the dose of vitamin D which caused complete healing was sixty-four times that which just failed to produce any visible calcification. When the differences in scale reading for doses of vitamin in the ratio 2:1 were averaged for large numbers of pairs of rats from the same litter, it was found that the mean scale difference was constant at about 1.9 divisions. Hence, although the dose given is increased twice at each step from the bottom of the scale, the degree of healing only increases two divisions at a time, in other words, the scale is approximately logarithmic in nature, the change in scale number produced by a given change in dose being directly proportional to the change in the logarithm of the dose. It is probable that this indicates that the rate of healing is proportional to the logarithm of the dose, at any rate over a limited range.

It was not found possible to use the scale without a standard preparation, owing to the great variations in sensitiveness of the animals at different seasons of the year, as well as between litters at the same season. They appeared to be most sensitive in summer and least so in autumn and winter. For the same dose of vitamin, the healing figure might vary six divisions on the scale at different times. The relationship between difference in dose and difference in scale reading was checked by selecting all rats which had shown a given degree of healing and then finding the scale numbers of all litter mates which had received half or twice this dose. The two sets of figures thus obtained were then averaged and indicated that, for the middle ranges of the scale, doubling or halving the dose produced a change of two scale divisions. Possible errors in this calibration were taken into consideration. The change of two scale divisions for doubling or halving the dose appears to be constant over long periods of time, but since it is possible that variations occur, it is advisable in routine testing to choose doses of unknown solution both above and below those of the standard.

In several recent investigations, attempts have been made to construct curves relating dose and effect in the case of other vitamins. The scale used by K. M. Key and G. K. Elphick for the assay of vitamin C bears the closest resemblance in type to that used by Bourdillon and his co-workers.<sup>2</sup> When guinea-pigs are given a scorbutic diet, changes occur in the structure of the teeth. Hoyer was able to recognise ten stages in the development of scurvy based upon these alterations. Key and Elphick, in re-examining these observations with the view of finding a basis for a quantitative method of assay, were only able to define five stages between scurvy and complete protection. Groups of young guinea-pigs were given a diet of bran, crushed oats, and dry skim milk with cod liver oil twice weekly. The experimental animals received also 0.75, 1.5, or 3.0 c.c. orange juice daily. The test was continued for fourteen days and the animals then killed. In this period, there were no differences in rate of growth amongst the experimental animals and the negative controls. The degree of scurvy developed in this time was only slight, although more definite in the latter. It was estimated by examination of transverse sections of the roots of the incisor teeth, the disease being characterised by disorganisation of the odontoblasts, the presence of an inner dentine, calcification of the predentine, and absence of Tomes' canals.

When the degree of scurvy was given a scale number

from 0 to 4, it was found that the average degrees of protection for groups of fifteen animals were 0.6 for the negative controls and 1.4, 2.4, and 3.9 for the groups receiving 0.75, 1.5, and 3.0 c.c. orange juice respectively. The relationship between dose and degree of protection is thus linear. In the case of vitamin D, as already stated, the linear relationship held between degree of healing and the logarithm of the dose. The authors found the response of individual guinea-pigs to be very variable. Consistent results could be obtained, however, when groups of five on each dose were employed. The method has the advantages of speed and of giving more precise results than that involving the determination of the minimum protective dose. The curve obtained can be employed as a standard of reference for the assay of materials containing vitamin C.

For the assay of vitamin A, which is usually tested by its growth-promoting power, a curve relating growth rate to dose given is required. It is possible that other methods may be developed in the future, for example, Coward has found that the number of rats dying when given small doses of the vitamin after a preliminary depletion period, during the second to fifth weeks of vitamin administration, is proportional to the dose given. The same observer has also published curves relating growth rate to dose of vitamin, from which it is possible to determine the potency of an unknown preparation in terms of a selected standard.<sup>3</sup>

It was found that the type of casein used in these tests played an essential part. A quantitative relationship between dose and growth was not obtainable when the casein used had first been heated. The synthetic diet was therefore prepared from 'light white casein', dextrinised rice starch, dried yeast, and a salt mixture. Small doses of vitamin D were given weekly or the diet was irradiated. The young rats were given this diet until they ceased to grow. They were then divided into groups, to each of which the same dose of cod liver oil was given daily by hand for five weeks. With doses ranging from 1 mgm to 7.5 mgm daily, the average growth rates varied from 2.0 gm to 10.0 gm per week for this period. The curve obtained by plotting growth against dose given was logarithmic in type; a simple formula could be fitted to it. It was later found that it could be resolved into two similar curves, one for the bucks and one for the does, the formulae for which are

$$y = 11.3 + 50.3 \log x \text{ (bucks) and } y = 12.4 + 27.4 \log x \text{ (does)}$$

where  $y$  is mean increase in weight of group in five weeks and  $x$  is dose of cod liver oil in milligrams

Analysis of the results showed that with five rats per dose the error is usually within fifty per cent, with ten, within thirty-three per cent, and with twenty, within three per cent. No seasonal variation in response was noted. The curve is used as a standard of reference in the assay of preparations of vitamin A. The growth responses to several doses of the latter are determined on groups of ten rats each and from the curve the doses of the standard cod liver oil which would have given such responses read off. The potency is proportional to the ratio of the dose of standard to that of the unknown at each level.

The necessity for an accurate biological test for vitamin A has been emphasised by some recent work on the possible chemical and physical characteristics of these vitamins.<sup>4</sup> It has been generally supposed that the blue colour given by an oil containing vitamin A with antimony trichloride is a good indication of its growth-promoting potency. The investigations of the above authors have now demonstrated that in cod liver oil at least two substances giving a blue colour are present. Comparative biological, chemical, and physical tests of a series of cod liver oils showed that the best agreement with the biological method was given by the measurement of the ultra-violet absorption band (at 3280 Å) of the oil itself, and also by that of the blue value of the unsaponifiable fraction of the oil. Less good agreement was obtained with the measurement of the intensities of the two bands present in the blue colour produced with antimony trichloride, while the least good agreement was shown by the measurement of the blue values of the oils themselves. In other experiments it has been shown that the intensity of the band at 5720 Å in the antimony trichloride test runs parallel with that of the band at 3280 Å in the oil. The intensity of the absorption at 6060 Å in the colour test shows no such relationship. This band appears to be due to the presence of another chromogen, its intensity is low in fresh oils but can be considerably increased by oxidation. It appears, therefore, that until the chemistry of vitamin A has been further elucidated, the final resort for its quantitative estimation must still be the biological test.

### Climate of Southern Rhodesia \*

THE meteorological service of Southern Rhodesia is, of course, in its infancy. Nevertheless, for the period under review 46 climatological stations and 550 rainfall stations were available, a network sufficient to give a good idea of the course of the weather. For the purpose of obtaining a general survey of the rainfall, the element which is of paramount economic importance to agriculture in such a region, the Report states that a gauge to each 120 square miles is sufficient. Southern Rhodesia contains about 1200 such squares, and of these, 322 are at present occupied by gauges. Just as in the case of the British Isles, the rainfall observers are

practically all voluntary helpers in meteorological work.

Rhodesia is one of those countries where the figure representing the average rainfall of any part for a long period of years is in itself a very uncertain guide as to the suitability of that region for particular branches of agriculture. The principal reason for this is the great variability from year to year of the fall in any part of the rainy season, but to this must be added the fact that much of the rain is received in violent storms—often accompanied by thunder—and the rain, even when of reasonable amount as judged by weekly or monthly totals, may be to a great extent lost to agriculture through the rapidity of its 'run-off'. Some striking examples of abnormal

\* Southern Rhodesia. Meteorological Report for the year ended June 30, 1930, by the Department of Agriculture. Pp. 94. (Salisbury.)

rainfall are given in this Report for example, 2.05 inches in fifteen minutes at Riversdale (Charter) on March 7, 1930, and 6.50 inches in one hour at Lundi (Chibi) on Jan 18, 1930. The latter figure represents very nearly the normal total for the wettest quarter of the year in London. It is natural that every effort should be made to forecast the amount of rain to be expected in each rainy season, and for this purpose it appears that a trial is being made of an equation connecting the general rainfall of Southern Rhodesia with the Nile Flood, pressure at Rio Janeiro, temperature at Mauritius, and minimum temperature at Bulawayo. The necessary values of the independent variables are not available until early in December, they give a combined correlation coefficient of +0.77 only, which is rather low for forecasting purposes. For the season 1928-29 the forecast departure from normal was -1.2 inches, and the actual departure -1.9 inches. This matter is in the experimental stage, and consequently the forecast was not made public.

The Report contains a good deal of statistical matter relating to the period under review, most of which is in tabular form. There are excellent rain-

fall maps, giving the geographical distribution of the year's total and of the normal year's total, both of which illustrate the general tendency for rainfall to decrease with distance from the Indian Ocean. This is a well-recognised feature of most of British South Africa, due to the fact that, apart from local convectional storms in the spring and occasional rains due to tropical hurricanes out on the ocean in late summer or autumn, much of the season's fall is due to dynamical cooling of the south-east trades as they rise over the elevated plateau of South Africa, which winds naturally lose much of their moisture in this way as they penetrate into the interior. Climatic investigation is being extended into the upper atmosphere by means of observations of wind with the aid of pilot balloons liberated at Salisbury. Some of these were followed to a height of ten kilometres. At the higher levels, the predominance of easterly and south-easterly winds appears to be lost, both in summer and winter, at ten kilometres, the directions most favoured in 1929-30 being west and north-west. Since this work was only begun in October 1928, this is the first full year's observations of upper winds.

E. V. N.

### Glasgow Meeting of the Chemical Society

**H**OLDING its annual general meeting at Glasgow on March 17, the Chemical Society paid its first visit to Scotland. The choice was particularly appropriate in view of the association both of the president, Prof. G. G. Henderson, and of the Society's first president, Thomas Graham, with that city, moreover, as Sir Thomas Kelly said at the civic reception, the Corporation has a particular interest in chemistry, for they themselves are chemical manufacturers on a very large scale.

In his presidential address, Prof. G. G. Henderson dealt with a matter of pressing importance to all societies which essay to publish the results of scientific investigation, and one which at the present time occasions acute anxiety to those organisations which are nobly attempting to continue to finance an adequate service of abstract publications out of the subscriptions of their members. The burden has fallen very heavily on the Chemical Society. The chief work for which it exists has grown very considerably during the past year, the number of original communications published in the *Journal* is 24 per cent higher than in 1930, and the number of chemical papers abstracted by the Bureau and published in *British Chemical Abstracts* "A" is also very much greater than in the previous year. The consequent financial burden is too great for the Society, with its present income, to bear, and at no other period in its long history has the Society been faced with such great difficulties in carrying on its work.

It is, and always has been, the function of the Chemical Society to encourage the development of chemical science in all branches and to provide a regular and complete record of all new additions to chemical knowledge, nevertheless, it was the Society of Chemical Industry, inaugurated in 1881, which gave to technological chemistry the stimulus then lacking owing to the restricted resources of the older Society, and afterwards the development of other branches of the science has been fostered by the creation of specialist societies. "Looking back on what has happened since 1841," said Prof. Henderson, "the thought arises that if those of our predecessors who managed the affairs of the Chemical Society during the first forty years of its existence had taken a broader and a longer view, some at least of the various

societies to which I have referred might not have been founded, and we might now have one great chemical society, with a membership of 10,000 or more, with the members organised into divisions dealing with the different branches of chemistry and possessing a large measure of autonomy."

Possibly the suggestion that an endeavour should be made to bring about the merging into one organisation of all the various societies concerned with chemistry might be considered impracticable, but Prof. Henderson urged that no effort should be spared to promote the closest possible co-operation between them, so far as the Chemical Society and the Society of Chemical Industry are concerned, a very good case can be made out for reunion. Such a union would almost indubitably effect economies, and the proposal *ipso facto* merits consideration. Even if the difficulties which stand in the way of bringing about a complete fusion of interests prove to be too great, it should be as possible as it is desirable to arrange for a working partnership of the most intimate character.

An important step in that direction was taken in 1923, when the Bureau of Chemical Abstracts—a joint committee of the two societies responsible for the production and publication of *British Chemical Abstracts* "A" and "B"—was formed. Upon these two societies alone falls the financial burden of this great work, a task which is performed for the benefit of every chemist in the country. Prof. Henderson pointed out that it is singular and anomalous that there are hundreds, perhaps even thousands, of professional chemists in Great Britain who make no contribution to this burden, who do nothing to help the cause of chemistry in the way that is most urgent, most necessary, and most expensive. He appealed to all chemists to support one or both of the two Societies, even though the *Journals* may be consulted by non-members in the general and departmental libraries of practically all universities and colleges, in the libraries of many chemical works and scientific societies, and in a number of public libraries, and even though they rightly find it desirable to subscribe to professional organisations such as the Institute of Chemistry and the British Association of Chemists.

A large addition to the membership of the Chemical Society would assist in easing the situation, but income derived from annual subscriptions is always subject to fluctuations, and something more permanent is desirable. Prof Henderson appealed for additions to the Society's capital fund, which supports the publication of the results of original investigations in chemistry, and in particular suggested that the Institute of Chemistry might not find itself precluded by its charter from widening the range of its beneficent influence by giving a substantial annual contribution to the Publications Fund of the Chemical Society. Referring to co-operation with the Institute and the Society of Chemical Industry in another direction, Prof Henderson advocated the formation of local committees of fellows of the Chemical Society in each city where there is a section of the Institute or of the Society of Chemical Industry, in order that joint meetings might be arranged for the reading and discussion of papers.

Of the various suggestions which have been made for the reduction of expenditure, that which proposed the abolition of the Bureau of Chemical Abstracts and the purchase of copies of *Chemical Abstracts* from the American Chemical Society is not likely to appeal to either of the societies. Another suggestion which deserves consideration, but is attended with risk of loss of income without marked diminution in the cost of publication, involves the payment by fellows of a nominal subscription, additional payment being made for whatever publications they desire to receive. A direction in which a certain reduction of expenditure could be effected was indicated by Prof Henderson. There is a tendency towards the publication of the results of research work in more numerous instalments than was formerly the custom, each instalment requires introductory discussion, and repetition is almost inevitable. If authors published their results in a more limited number of more comprehensive papers and safeguarded priority by means of short communications, little if any loss would be suffered and valuable space would be saved.

The problems discussed by Prof Henderson are very real and their solution will be correspondingly difficult, nevertheless, it may be supposed that members of a great scientific community will approach them boldly and skilfully as a profession, and not sectionally or with hesitation, unity is strength, and success proverbially comes to the strong.

During his speech at the anniversary dinner after the meeting, Lord Weir referred to a matter of policy which has frequently been emphasised in the columns of *NATURE*—the status of science in politics and the nation's neglect to make adequate use of scientifically trained men in high places. The man of science must nowadays be mainly a specialist, accordingly, the politician or the so-called business man becomes the framer and controller of policy. While admitting great respect for both the politician and the business man, Lord Weir doubts whether sufficient use is made of the trained scientific intellect when the major lines of national policy are being decided upon. Experience has taught him, for example, that at no time should the Board of Admiralty, the Air Council, or the Army Council—any one of them—be without a member having scientific or engineering attainments, he referred to no question of status or recognition, but the simple wisdom of having representation of that type of brain. Whether or not this is a matter which can be appropriately pursued by the Chemical Society is for that organisation to determine, there can, however, be no two opinions concerning the place of exact knowledge and organised inquiry in the art and practice of government.

## University and Educational Intelligence

OXFORD —The School of Geography at Oxford was established, with the assistance of the Royal Geographical Society, in 1899. In 1921 it entered into possession of its present quarters in Mansfield Road, where lectures and practical and tutorial instruction are given and other geographical work is carried on. For some years past a diploma in geography has been granted by the University to qualified candidates, and it has lately been decided to raise geography to the status of a final honour school for the arts degree. A new professorship has been established, and the first holder of the chair will be Major Kenneth Mason, who has a distinguished record for service in France, Persia, India, Mesopotamia, and Central Asia. He will be an *ex officio* fellow of Hertford College. The conditions and regulations for the new honour school are not yet determined. Major Mason will take up his duties on May 1.

ST ANDREWS —The Senatus Academicus has agreed to confer the honorary degree of LL.D. upon the following, amongst others, on June 28: Sir James Frazer, Sir Richard Livingstone, vice-chancellor of the Queen's University of Belfast, Mr James Robb, secretary of the Carnegie Trust for the Universities of Scotland, Prof L. R. Sutherland, emeritus professor of pathology in the University of St. Andrews.

MR W. E. SHEWELL-COOPER, horticultural superintendent, Cheshire County Council, has been appointed horticultural superintendent at the Horticultural College, Swanley, and will take up his duties in July.

At the National Union of Teachers' annual conference at Folkestone, the president, Mr A. E. Henshall, of Stafford, protested energetically against the postponement of school building programmes, the employment of capacity tests for free places in secondary schools, and the 'cuts' in their salaries to which teachers have recently been subjected. The teachers of the country, he stated, continue to believe that they have been harshly and unjustly treated. As regards the services the teachers may be expected to render to the community, he directed attention to the difficulty of preparing pupils for life in a rapidly changing world, and suggested (somewhat optimistically) that the teacher can train them to seek to use their own powers, lead them to exercise initiative and to achieve self-reliance, and cultivate open-mindedness, intellectual curiosity, accuracy of thought, tolerance, and a sense of personal responsibility. The time has arrived, in Mr Henshall's opinion, for a reconsideration of the relation between school and workshop, for no education can be complete which disregards the need of earning a livelihood. Increased leisure, "the gift of science", must also be prepared for, and in the schools must be cultivated interest in those arts and crafts the practice of which demands only relatively easy technique but provides means of self-expression. The May Committee is blamed for checking progress in this direction.

UNTIL quite recently, science as a subject in a girl's education received scant attention. Towards the end of last century, if in the school curriculum at all, it consisted chiefly of descriptive botany and some geology. The method was therefore essentially didactic. At the beginning of the present century the pendulum began swinging in the other direction and laboratory work was initiated. A preliminary drilling in physical measurements formed the basis of this scientific way of obtaining knowledge by personal observation and experimentation, but this heuristic

method proved to be very slow. As Miss I. M. Drummond, former president of the Association of Women Science Teachers, points out (Association of Women Science Teachers, Report for 1931), it is impossible to force ontogeny to repeat phylogeny in educational method. Progress by such a method would be tedious and defeat its own ends. It is necessary to keep in view the sciences and the greatness of scientific conceptions. The practical method is still essential, and experiments, while they are a means of illustration, should not be treated merely as such, but rather as the basis of the lessons. Thus results would come as surprises, and force the individual to trust her own powers of observation. Training in accurate expression, too, comes via the laboratory practical notebook. Teachers have in their hands an instrument of pre-eminent value for training real integrity of the mind. The cultural value of science can be brought out through its past glories. The history of science has a twofold value in endowing science with a human interest and enabling our people to cultivate the mental equipment necessary for the present-day scientific atmosphere of thought.

### Calendar of Geographical Exploration

#### April 4, 1931—Haardt's Last Journey

M. Georges Marie Haardt, the famous French explorer, set out from Beirut, Syria, on an attempt to cross Asia by motor car. The journey was successfully accomplished, and Peking reached on Feb. 12, 1932, but the explorer contracted pneumonia and died at Hong Kong in March. Iraq, Afghanistan, the Indus valley, and the Pamirs were traversed, but travel by motor had to be abandoned after ascending the Bourzil Pass to 13,775 ft., the heavy rains compelling the party to take to ponies and yaks. In one place the motors had to be taken to pieces and reassembled, in order to avoid the effects of a landslide. M. Haardt had made many previous overland journeys, the most famous being the crossing of the Sahara in 1922-23, which resulted in the opening up of new routes between Algeria and the Niger.

#### April 5, 1752—South-East Africa

An expedition led by A. F. Beutler, and including among its members two surveyors and a botanist, reached the last settlement towards the east from Mossel Bay, just beyond the Little Brak River. Keeping near the coast, the party explored the shores of Algoa Bay, crossed the Great Fish River, and arrived at the Keiskama River, which then formed the boundary between the Hottentot and Bantu peoples. The Kei River was crossed, but the fatigue of the party then made return necessary. A different route was taken, and much new country, including the valley of the Fish River, was explored.

#### April 6, 1682—The Mississippi Delta

Robert Cavelier de la Salle reached the Mississippi delta. La Salle went to Canada in 1666, and in 1669 began his famous series of explorations by discovering the Falls of Niagara and the Ohio River. The discovery of the Mississippi River was made by Joliet and Marquette, who reached it via the Wisconsin, but turned back near its confluence with the Arkansas. La Salle, with two companions, set out in December 1681 from Fort Miami, descended the Illinois in canoes, and reached the Mississippi in February 1682. On April 6, when they reached the head of the great delta, each of them sailed down a separate arm and met later in the Gulf of Mexico. In July 1684, La Salle attempted to reach the delta by sea, but landed

in the lagoons of Texas, 400 miles from it. His store ship and its companion vessel were wrecked. An attempt to lead his discontented party overland resulted in the murder of La Salle and three others of the party in the plans of Texas, before the valley of the Mississippi was reached.

#### April 6, 1909—The North Pole Reached

R. E. Peary, the American Arctic explorer, reached the north pole, accompanied by the negro Henson and by four Eskimos. They remained there about thirty hours, and in a sounding a few miles from the pole found no bottom at 1500 fathoms. Peary started on this journey in 1908, wintered in Grant Land, and set out over the ice from Cape Columbia on March 1, 1909. A party of six set out and were gradually sent back as supplies diminished, Bartlett turning back at 87° 48' N. Peary began his work in 1886, when he made a study of Disco Bay on the west coast of Greenland as a possible base for polar exploration. In 1891 he undertook a polar expedition, his wife accompanying him, and in 1892 reached the north-east coast of Greenland, thus proving it to be an island. Studies were also made of Smith Sound Eskimo tribes. In 1902 Peary and Henson reached 84° 17' N., and in 1906 Peary and his companions reached 87° 6', but were compelled to return at that point. His success in 1909 crowned twenty-three years of continued effort.

### Societies and Academies

#### LONDON

Society of Public Analysts, Feb. 3.—N. L. Allport and G. H. Skrimshire. A new method for the determination of lead in organic substances, with special reference to dyestuffs. The organic material is destroyed by wet oxidation and the lead is removed by shaking with a chloroform solution of diphenylthiocarbazone. Finally the lead is determined colorimetrically as sulphide. The method is applicable in the presence of large amounts of iron, but bismuth interferes with the method, and special procedures are necessary when appreciable amounts of tin, aluminium, nickel, or cobalt are present.—B. S. Evans. (1) Some analytical applications of sodium hydrosulphide. A rapid and accurate method is described of separating tin from various other metals the sulphides of which are soluble in alkali cyanide. (2) A rapid method of dissolving lead alloys preparatory to the determination of tin and antimony. Lead dissolves rapidly and completely in a mixture of perchloric and phosphoric acids, whilst tin and antimony form insoluble compounds which are apparently of the nature of 'metastannic' and 'metantimonic' acids.—H. B. Dunnick and H. D. Suri. The phloroglucinol method for the determination of mechanical wood pulp in paper. The phloroglucinol method of Cross and Bevan was found to be unreliable in India, and the authors have therefore studied the effect of temperature on the results, the relationship between the volume of standard reagent and the weight of paper for quantitative reactions, the time required, and the mechanism of the reaction.—E. H. Bunce. Investigations relating to milk standards under the Burma Food and Drugs Act. There are no legal standards for milk in Burma, but in the Government Laboratory a minimum of 3 per cent of fat and 8.5 per cent of solids-not-fat is adopted for cow's milk, and a minimum of 5 per cent for fat and 9.0 per cent for solids-not-fat for buffalo's milk. A common fraud is the dilution of buffalo milk with water to imitate cow's milk.

## DUBLIN

Royal Irish Academy, Jan 25.—J. J. Nolan and J. G. O'Keeffe Electric discharge from water drops. The negative discharge from drops originally hemispherical exceeds the positive for the same field values. Rapid discharge for drops of radius  $r$  exposed to a uniform field  $F$  begins for values of the field given by the approximate relation  $F\sqrt{r} = 3600$ , the units being volt and centimetre. In a pure atmosphere the ions produced by the discharge remain small ions.

## PARIS

Academy of Sciences, Feb 15.—B. Bang was elected *Correspondant* for the Section of Rural Economy.—Bertrand Gambier The points of contact of an algebraic curve and its envelope.—Gaston Julia The prolongation of a Riemann  $\sigma$  surface corresponding to a multiple convex area  $\mathcal{Q}$ .—N. Théodoresco The employment of Hadamard's method in the solution of Cauchy's problem for certain systems of partial differential equations.—René de Possel Ensembles of the maximum type and the prolongation of Riemann surfaces.—Henri Milloux An inequality of the theory of functions and its applications.—Jean Louis Destouches The integration of the equation with the first integrals of quantum mechanics.—André Coyne A new method of testing concrete or reinforced concrete works, especially barrages, by means of sound. A stretched steel wire is fixed between two points, by an electromagnetic arrangement and amplifying valves, any change in the distance between the two fixed ends of the wire can be measured in terms of beats heard in a telephone, the note emitted by the wire being compared with a standard tuning-fork. Numerous problems of interest to which this method can be applied are indicated.—Edmond Brun and Pierre Vernotte The heating of a thermometer by a gaseous current. Aerodynamical applications. The heating observed is the quotient of two complex phenomena, friction and convection. A theoretical formula is developed which gives a rise of temperature of the same order as that actually measured.—M. Mendes The problem of  $n$  bodies with variable masses.—A. Portevin and P. Bastien The principal factors affecting the flow of pure metals. The flow is the resultant of several complex factors, in which the calorific properties (specific heat, latent heat, melting point) of the metals are at least as important as the viscosity.—G. Reboul A particular form of activity of matter. Study of the action of various substances on a photographic plate.—Marcel Dufour The suppression of astigmatism in oblique pencils in thin lenses.—J. Gilles The relations between the quadruplets corresponding to N(I), O(II), S(II), and Cl(III).—E. Stahel The number of the secondary  $\beta$ -rays emitted by radium. For every 100 atoms decomposed, 5 secondary  $\beta$ -rays are emitted. This leads to the unexpected conclusion that the greater part of the radium atoms decompose without emitting  $\gamma$ -rays (see also NATURE, Feb 27, p 314).—E. Calvet The velocities and heats of saponification of the amides.—Adrien Karl The estimation of radium in the presence of the sulphates of the alkaline earths. The radium barium sulphate is heated with the eutectic mixture of sodium, potassium, and lithium chlorides to a temperature just above the melting point ( $520^\circ\text{C}$ ). No vapours are given off, and the emanation can be readily removed in a current of air.—Jarry The extraction of the phenols in tar oils by liquid ammonia. A mixture of tar oil and liquid ammonia separates rapidly into two layers: the upper layer contains the whole of the phenols.—Marcel Godchot and Max Mousseron Some new piperazine derivatives.—S. Sabetay and D. N. Mira Some ether

oxide aldehydes.—L. Royer New observations on the orientation of crystals deposited in contact with a cleavage of mica or chlorite.—F. Dupré la Tour Studies on the dimorphism in the normal saturated fatty diacid series as a function of the temperature.—M. G. Filipesco The siliceous accidents of the Tisara strata (Flysch of the Roumanian Carpathians).—Dalloni The volcanoes of Tibesti.—André Demay The conditions of orogenesis and of Hercynian metamorphism in the eastern edge of the central massif between Saint-Vallier and Privas.—Ch. Gérard A Liassic fauna of Sierra Sagra, in the sub-betic zone (southern Spain).—G. Corroy The Toarcian of Lorraine and of Haute-Savoie. The recurrence of the schistose facies at Posidonomyes.—Antonin Lanquine The extension of the facies and fauna of the Argovian in the Provençal chains.—Mlle Lucienne George Observations on *Sorbus aria*.—J. Dufrenoy Correlation between the air temperature and rate of growth of the vine.—L. Grigorakis The morphology and evolutionary cycle of the Actinomyces.—H. Colin and P. Ricard *Pelvetia canaliculata* as a source of l-fucose.—Émile Andre and Kiawo Hou The presence of a lipide oxidase or lipoxidase in the seed of *Glycine soja*.—Marcille Life in a confined medium. Protection against poison gas.—Mme L. Randoin and Mlle A. Michaux Variation of the amount of sodium and potassium in striated muscle under the influence of a diet entirely deprived of the antiscorbutic vitamin. The absence of vitamin C from the diet causes an increase of the sodium and chlorine in the muscle and a reduction of the potassium.—Raymond-Hamet The action of acetylcholine on the vasomotors of the penis in the dog.—H. Bierry and B. Gouzon The fluorescent substances of egg-shell.—Étienne Rabaud The rôle of the *stabilimentum* in the webs of *Argiope bruennichi*.—Mlle Yvonne Garreau and J. Parrot The oxidation products of *d*-galactose by ammoniacal copper oxide and the oxygen of the air, at laboratory temperature.—G. Delamare and C. Gatti The rounded bodies of *T. dentrum*.—C. Levaditi and N. Constantinesco Syphilis and neoplasms.

## VIENNA

Academy of Sciences, Nov 11.—R. Weiss and C. Alberti The action of benzyl magnesium chloride on benzal phthalide. (2) Preparation of *o*-phenylenebis-(phenylglyoxal).—K. H. Berg Cytological observations on *Aegilops truncialis*  $\times$  *Secale cereale*.—K. H. Berg A hybrid with four complete haploid species-genomes.—A. Winkler Preliminary report on studies in the Tertiary on the north-east spur of the central Alps.

Nov 19.—R. Weiss and A. Abeles The separation of racemates into their optically active components by means of addition-compounds.—H. Bojko The ecology of *Cynodon dactylon* and *Astragalus exscapus*.—A. Kohler Geological and petrographic investigations on the primitive rocks of the Lower Austrian Waldviertel and its boundary regions. Second report. Two new analyses of granites.—K. Girkmann Dimensions of girder frameworks on the assumption of an ideal plastic steel.—M. Mladenovic Elemic acid from Manila elemi resin. (4) Dihydro-elemolic acid and its derivatives.—K. Cori and B. Finzi Enumeration of the ants collected by K. Cori on the South Dalmatian islands in 1914.—E. Holesch The evaporation of radium-*B* and radium-*C* in hydrogen and nitrogen.

Nov 26.—F. Ackerl The gravitational field of force of the earth. A map has been prepared with lines of equal force.—F. Kuba Centric crank oscillations.—L. Kolbl Tectonic of the Tauern 'fenster'.—H. Y. Graben Report on geological and petro-

graphic researches in the Upper Austrian primitive rocks—M Sellnick Zoological expedition to the Ionian Islands and the Peloponnesus (10) Acari—A. Zinke and O Benndorf Perylene and its derivatives (34) The hydration of perylene—Eder, Spath, and Wegscheider Commission report concerning the discovery of red phosphorus There have been two claimants, Dr J Goldmark and Prof A Schrotter Schrotter's experiments began in 1845 Goldmark was a student in Schrotter's laboratory between 1845 and 1847 Goldmark lectured on red phosphorus in August 1847 at Oedenburg in Hungary Schrotter's first announcement was to the Vienna Academy in November 1847, published in December 1847. The commission awards priority to Schrotter.

### Forthcoming Events

#### FRIDAY, APRIL 1

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual General Meeting) (at Engineers' Club, Manchester), at 7—F J Slee. Laboratory Tests of Lubricants and their Relation to Engine Tests (Lecture)  
MANCHESTER ASSOCIATION OF ENGINEERS (Annual General Meeting) (at Engineers' Club, Manchester), at 7—W Core Layout of Machines and Small Tools for Economical Production

#### MONDAY, APRIL 4

ROYAL INSTITUTION OF GREAT BRITAIN, at 5—General Meeting  
INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (Annual General Meeting) (at Birmingham University), at 7—E A E Woodward and W A Carne An Analysis of the Costs of Electricity Supply and its Application in Relation to Various Types of Consumers  
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Royal Institution), at 8—Sir William Bragg and Dr G Shearer The Application of X-Rays to Chemical Industry (Lecture)

#### TUESDAY, APRIL 5

ROYAL ANTHROPOLOGICAL INSTITUTE (African Research Committee), at 5 30—Culture Distribution Maps for Africa  
LONDON NATURAL HISTORY SOCIETY (at London School of Hygiene and Tropical Medicine), at 6 30—Prof M Culpin Heredity and Disease (Bacot Memorial Lecture)

#### WEDNESDAY, APRIL 6

ROYAL SOCIETY OF ARTS, at 8—Dr F H Constable Light Sensitive Cells in the Service of Man (Lecture)

#### THURSDAY, APRIL 7

INSTITUTION OF CIVIL ENGINEERS, at 6—To consider a Provisional Report of a Sub-Committee of the Institution on the Drafting of Bills of Engineering Quantities, together with a List of the Units of Measurement to be Employed

#### FRIDAY, APRIL 8

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30—Sir Richard Burn Recent Developments in Land Revenue and Rent Policy in the United Provinces (Lecture)  
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Royal Victoria Hotel, Sheffield), at 6—T G Elliot and Dr W Cullen Special Alloy Steels as applied to Chemical Engineering  
INSTITUTE OF FUEL (East Midlands Section) (Annual General Meeting) (at University College, Nottingham), at 7 15—V B Harley-Mason Conditioning of Boiler Feed Water  
SOCIETY OF DYERS AND COLOURISTS (Scottish Section) (Annual General Meeting) (at George Hotel, Glasgow), at 7 15—J Muir Some Notes on pH Control by Colorimetric Methods (with demonstrations)

No 3257, VOL 129]

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at College of Technology, Manchester)—Annual Meeting.

#### APRIL 8 TO 11

CONGRESS OF GERMAN PHARMACOLOGICAL SOCIETY (at Wiesbaden)

#### APRIL 11 TO 14

CONGRESS OF GERMAN SOCIETY FOR INTERNAL MEDICINE (at Wiesbaden).

## Race and Creed in the Problems of India

SINCE our issue of Jan 23, when the problem of India was last the subject of comment in these columns, the progress of events has been far from reassuring. It is no exaggeration to say that the results of the deliberations of recent years seem to be well on the way to the melting-pot. It is true that the pledge of Britain to India to press on constitutional reform still stands, but India, on its side, has made little contribution towards a settlement. The problem of the communities remains unsolved, yet this is the problem for which, it has been laid down, a satisfactory solution must be found in the settlement of the franchise as a pivotal and precedent condition of all reform.

When the delegates to the Round Table Conference returned to India, early in the year, they felt able to speak with some assurance of the possibilities of reform. They were inspired with a confidence born from the expressions of goodwill to which they had listened in London. That confidence has now vanished, and it has vanished at the bidding of their own people. It is apparent that there is little inclination in India towards that compromise between diverse interests which, with all the goodwill in the world, is inevitable in any formula of government that aims at securing a justly representative character in the institutions it regulates. The course of affairs in India is again approaching a deadlock.

It must be pointed out once more—and apparently it cannot be pointed out too often—that the situation in India, which becomes a deadlock when an attempt is made to come to grips with practical measures, is not a political crisis which can be resolved on the lines of compromise and arrangement possible in a western civilisation. The attempt to mould the oriental mind to western ideals has produced the present difficulties in India, those ideals have not permeated Indian life and thought to the degree necessary to make it possible to deal with these difficulties on western lines. Social and political compromise as the result of a voluntary approach one to another, which is of the essence of western political life, is impossible between race and creed in India.

To admit this factor in the situation is not necessarily to adopt a counsel of despair, but it is necessary that it should be clearly understood. The spectacle of a united but shackled India, debarred from self-government by the British *raj*, has vanished. The British Government has declared its willingness—and even India must

admit its sincerity—to grant self-government to the Indian people. It is the Indian peoples themselves who stand in the way. Their attitude of mind is not one that is readily comprehensible to the average western; but it is from the point of view of the oriental mind that the problem must be attacked. Notwithstanding India's advanced civilisation and the long history of its culture, the problems of its government must be studied by its administrators, and by those who ultimately will have to submit its fate to the arbitrament of the British Parliament and the British people, in the light of principles formulated by anthropological science and after consideration from the trained and sympathetic point of view of the anthropologist, just as much as the social organisation and the religious beliefs of the Negro races have been studied and taken into account in the administration of West African affairs. India must be governed according to Indian ideas, but not the ideas acquired by a western veneer.

What are the racial or sectarian ingredients of the problem? Hindus, Sikhs, Moslems, all are animated by an antagonism one to another, which is capable at any moment of bursting into a flame, all the more intense because it is nearly akin to religious fanaticism. The recently issued report on the trouble between Hindu and Moslem in Kashmir describes the latest and by no means the least disturbing of these outbreaks—disturbing not merely on account of its extent, but also because it is one of a series of disturbances differing in character from the faction fights in which Moslems previously had been concerned. Hitherto, at periods of political difficulty and stress affecting the Moslem communities, the authorities had always been able to rely on their loyalty. They can rely upon them no longer.

To this list of inflammable material must now be added the outcastes, and above all, the untouchables, the depressed classes, bitterly resentful of the attitude of the castes—Hindus, who ostracise them, while at the same time claiming, for political reasons, that they must count as Hindus without rights to separate consideration. Each of these groups, however, is vocal. It may hope for an expression of its views and aspirations, if only after filtration through a disproportionately small selection of its numbers. But what of those who are classified by the Census authorities as animists, the wild tribes who fit into no category, but whose beliefs and whose village godlings are slowly being assimilated to the Hindu pantheon? Are they to be absorbed into the Hindu community? Their

claims are least likely to be heard, yet to the scientifically trained observer their institutions and their beliefs demand the most careful consideration, lest injustice may follow under even the most benevolent of administrations.

Each of these sectional interests has its own traditions and its own outlook, to which deference must be paid. A recent case which has attracted much attention may serve to illustrate the pitfalls of action and reaction between these sectional differences in outlook. This is the case of the two Moslem youths condemned to death for the murder of a Hindu bookseller. The exaggerated and highly inflamed state of sectarian feeling was, no doubt, largely responsible for their act, but its immediate cause was the fact that the bookseller had displayed a portrait of the Prophet in his store. This was a gross offence to the Moslem creed. In this connexion the incident carries its own moral and needs no elaboration.

It cannot be said that the situation has been seriously affected in an adverse sense by the drastic action of the executive in the suppression of disorder. In fact, the result, on the whole, has been rather the reverse. The ingrained inclination of the Oriental to hold in respect the strong hand, without too much regard to the motives with which it is exercised, has tended to weaken the position of the Indian Congress. Especially is this apparent in rural areas. Here, indeed, the position of the Congress was by no means too strong. Although its propaganda among the peasant cultivators was a serious source of danger, the 'no dues' campaign and the claim to decide upon the readjustment of terms of land tenure were, naturally, by no means so popular among the landholders as they were among the peasants. The fact that an 'unofficial' pamphlet advising the payment of government dues, which has been circulated among the peasant tenants in one area, has not been repudiated is surely indicative of a weakening in the position of the Congress.

In the meantime, the attitude of the native princes has not been without its effect in obscuring counsel. Their acceptance of the principle of adherence to an 'All-India' federation appears to have been by no means so generally agreed among them as was stated, and the pending election of a chancellor of the Chamber of Princes added a measure of uncertainty as to their ultimate decision. After a period of vacillation, it became apparent that they had in mind a degree of co-operation in a federated India as essential to their interests, though it was by no means evident that

they had any very clear idea as to the form or extent of their adherence. Discussion of the report, which had been prepared for the consideration of the Chamber, evoked something more nearly approaching the nature of a definite policy. At the time of writing it seems possible, however, that they will for the present go little beyond their original expression of adherence, subject to the safeguarding by the Crown of all treaty rights and rights of internal sovereignty. Once more the real difficulty, as always in India, that of practical detail, is likely to be left untouched.

All things considered, the work of the advisory committees, from which so much was expected, has not been pursued in the happiest of circumstances. It was thought that, while they considered specific problems on the spot, intimate contact with local conditions would assist them in arriving at their decisions. Unfortunately, it has proved once more that distance not only lends enchantment but also adds perspective. Quite early in the discussions it became evident that there was a strong inclination among the Indian members of the committees to refer back the more difficult problems for consideration and decision in London. The Consultative Committee, in fact, when it adjourned late in February, pending the submission of reports from the other committees, had accomplished little.

So far as one of the committees is concerned, the Franchise Committee, it is evident that delay is inevitable before the report can be considered. An attempt was made to stampede the Moslem Congress, which was held at Lahore on March 21, into a boycott of the Round Table Conference and the withdrawal of the Moslem delegates, on the ground that towards the end of February the Moslems had asked Lord Willingdon to submit the communal question to the British Government for decision, in view of the impossibility of arriving at a solution in India, but that apparently nothing had been done. Actually the request had been transmitted to the British Government by the Consultative Committee through the Governor-General, and an announcement was issued at Delhi on March 19 by the British Government, acknowledging with regret the notification of the Consultative Committee and reiterating the statement made in December last that, in the event of no communal agreement being reached, this failure would not be allowed to stand in the way of reform and a provisional solution would be imposed by the British Government from above. Although the Moslem Congress was by no means united, and

the action taken was due to the more extreme members, in view of this announcement it was decided that the matter of the boycott should not be pressed, at least for the present.

Once more the ball rests with Great Britain. It cannot but be felt that the occasion, if on one hand an embarrassment, on the other offers a great opportunity. The Government, it is true, has nothing in the nature of a mandate from India, but it has behind it the cogency of facts and the request of a not inconsiderable section of the community—in influence, if not in numbers. It is justified in taking the view that, in dealing with a practical problem such as the communal question, the political sense of the Indian peoples has proved itself utterly sterile. The natives of India, like other oriental peoples, can appreciate and render loyalty to a strong leader, they understand and accept domination of the weaker by the strong, provided the policy of non-interference with custom and belief is followed. They do not as yet understand, and cannot yet of their own initiative contribute towards, a settlement on the give-and-take lines of western democracy. The imposition of a settlement from above, however provisional in character, and always assuming that its adoption and observance are pressed with firmness, will constitute a greater advance towards the ultimate reform than all the endless and fruitless discussions by which an attempt has been made to elicit a common denominator for the aspirations of the people themselves. Stress has sometimes been laid on the measure of success in administration achieved in present conditions. This very fact is not without its significance, for it has been achieved under the ægis of restraining authority, which has given to sectarian feeling the balance it has not been able to attain by itself.

India, it may be recalled, is a great and growing industrial and commercial community. While this complicates, it does not alter the fundamental character of the problem. Its solution lies not with the urban but with the rural population, to which the predominant number of the Indian peoples belong. Reform will come not from above by the imposition of western institutions in the hope that their influence will permeate downwards, but by building up from below, by the careful scientific study of village institutions and their gradual modification to meet the strain of changing conditions as standards change, as change they must inevitably in the end. To take the first step in this direction the British Government has now been given the opportunity and the occasion.

### Berkeleyan Biology

*The Philosophical Basis of Biology* *Donnellan Lectures, University of Dublin, 1930* By Prof J S Haldane. Pp x+169 (London Hodder and Stoughton, Ltd, 1931) 7s 6d net

PROF J S HALDANE'S Donnellan lectures at Trinity College, Dublin, are here offered to the public in the form of a small book of some 170 pages. Biologists will read them with that extraordinary mixture of admiration for the author and exasperation at his views which they have now long been accustomed to experience.

The book is divided into three sections, the first of which bears the challenging title "The Axiom of Biology". As Berkeley inquired whether there is any meaning in the physical universe apart from its being perceived, so Prof Haldane wishes to inquire whether any meaning can be attached to the concept of an organism apart from its environment. It is obvious, he says, that in the biological sciences we are always making use of words such as 'function', 'organ', 'species', which are quite peculiar to biology and have no analogy in the physico-chemical sciences. These words cover a residuum (the major part of biology) for which no physico-chemical description has ever been found. Indeed, "the more we discover as to physiological activity and inheritance, the more difficult does it become to imagine any physical or chemical description or explanation which could in any way cover the facts of persistent co-ordination" (p 12). We cannot separate organic from environmental structure, for no sharp line of demarcation can be drawn between the organism and the environment. So we come to Prof Haldane's axiom: "The active maintenance of normal and specific structure is what we call life, and the perception of it is the perception of life. The existence of life as such is thus the axiom on which scientific biology depends".

It seems profitless to criticise this point of view, for scarcely any modification has taken place in Prof Haldane's opinions since the days of his paper in Andrew Seth's collaborative "Essays in Philosophical Criticism" (1883). His brilliant physiological researches have been carried on side by side with an attitude to biological phenomena which can only be likened to that of Frascatorius of Verona—"The heart's motion God alone can comprehend". Time after time Prof Haldane in these lectures appeals to the argument from inconceivability, thus joining hands with a thinker from whom he is usually careful to dissociate himself,

namely, Prof Hans Driesch. With respect to environment, his demand for the unification of organism and surroundings is surely a methodologically impossible aim, for if no line can be drawn between organism and immediate surroundings, no better line can be drawn between immediate surroundings and far-off surroundings. Biology is thus brought under the rule not only of Berkeley but also of Plotinus, and we are invited to contemplate the whole universe in its axiomatic wholeness, analysis of living things being laid aside.

The solid foundation for Prof Haldane's position, the real burden of his emphasis during so many years, is of course that the problem of organisation is the central problem of biology. "When we discover, for instance", he says on p 79, "the existence of an intraprotoplasmic enzyme or other substance on which life depends, we are at the same time faced by the question how this particular substance is present at the right time and place, and reacts to the right amount to fulfil its normal functions". Or again (p 16), "Physical or chemical mechanisms within the living body are actively maintained at the right places and in the right functional states". But to take organisation in biology as axiomatic is as fruitless as it would be to take the chemical elements as axiomatic in physics, and to make no attempt to go behind the periodic table into the realm of the electronic structure of atoms.

It is, no doubt, metaphysically true to say with Dr Tennant, that "the illogical core of the world is not a mere residuum of haze which science, when ideally perfect, shall have dissipated", the arbitrariness of the universe is indeed irremediable, but the worst mistake that can be made in scientific methodology is to introduce this arbitrary element at a higher level than absolutely necessary. If we take living organisation as axiomatic, that is, as an essential part of the impenetrable illogical core of the world, we at once discourage such investigations as the X-ray analysis of the relation of protein molecules one to another, which seems at present so likely to afford us an insight into the mechanism of cytoplasmic differentiation. Can we suppose that the students of colloidal physics have as yet said their last word (or even their first word) on the subject of protoplasm? The sublime expression "I am that I am" is well suited to the manifestation of a deity, but when applied to the immediate problems confronting scientific workers, its use becomes nothing more than the frank confession of intellectual bankruptcy.

Characteristic of Prof Haldane's self-contradictory position is the contradiction between p 11 and p 22. On p 11 we are told that the central facts relating to the specificity of a species are part of the residuum which physico-chemical biology is powerless to touch. Yet on p 22 "the constitution of proteins, including hæmoglobin, which can be separated from the bodies of different individual men, varies appreciably between different individuals, and this is no mere accidental circumstance, but is as characteristic for the individual as the shape or size of his hands or face, or the colour of his hair." Two thinkers struggle perpetually for the possession of Prof Haldane: one, the exact biologist, full of desire for the metrical description of phenomena, and for their causal explanation; the other, the idealist philosopher, primarily concerned with making the world safe for the spirit, and not averse from immediate appeals upon emergent occasions to the illogical core of the universe. It is for failure to differentiate between the two constituents of this dual personality that successive generations of biologists have been vexed and irritated by the counsels of one of the greatest among them.

One of the points upon which Prof Haldane lays much emphasis in these lectures is the fact that the assumed basic conceptions of Newtonian physics have been shown not to be in reality basic, and that instead we are presented with facts (for example, the intense co-ordinated specific activity within the atom, which does not become dissipated in its environment, and upon which its mass and other properties depend) which bear some resemblance to those with which biologists are familiar. This is undoubtedly very important, and no one is yet in a position to say what the influence of the quantum theory and wave mechanics may be upon biology, but Prof Haldane, curiously blind to these possibilities, can only infer from the breakdown of Newtonian physics the breakdown of physico-chemical biology. To more unbiased observers, the vanishing crudeness of chemistry seems to make the future of biochemistry all the more hopeful.

Another matter upon which Prof Haldane has a methodological theory all his own is the omission of 'essential' facts from scientific hypotheses. "Consciousness", he writes on p 87, "can certainly be treated from a purely mechanistic standpoint if we pay no attention to essential facts, just as other sides of physiology can be so treated when essential facts are left out of account." The only thing lacking here is a definition of the word

'essential', and there seems no logical distinction between Prof Haldane's position and that of a theologian who would object to the discussion of consciousness without reference to the facts of religious experience. This leads to an underestimate of the work of Prof Pavlov and his school, as several students of Prof Haldane's writings have recently remarked. To make use of an Eddingtonian phrase, when Prof Haldane says "mind" he means "mind (loud and prolonged applause)", that is, "mind" in the sense of Berkeley and Bosanquet, not in that of Herrick and Pavlov.

At the conclusion of his book, Prof Haldane devotes a special appendix to the discussion of Mr Woodger's "Biological Principles", Dr Russell's "Interpretation of Development and Heredity", and Prof Hogben's "The Nature of Living Matter". On the last named he pronounces an expected excommunication, on the second he sets the seal of probable orthodoxy, and the first he lays aside as a doubtful case, with a recommendation to mercy. It would scarcely be possible here to criticise the critic, and a mere reference to the appendix must suffice.

Prof Haldane is assured of an honourable place in the history of biology in the late nineteenth and early twentieth centuries. But this will always be in spite of, and not because of, his presentation of his case. It will be said of him that he took biological organisation seriously when no other biologist would, but perhaps this recalcitrance on the part of his colleagues was partly due to his own inability to distinguish between the conflicting claims of science and philosophy, and, we may add, of religion also.

JOSEPH NEEDHAM

### Technical Education in the Soviet Union

*Industry and Education in Soviet Russia*. By J. G. Crowther. Pp xi+94+16 plates. (London. W. Heinemann, Ltd, 1932) 7s 6d net.

WITH the publication of his "Outline of the Universe", J. G. Crowther may be said to have arrived as a writer of popular science. Contemporary writers on science for the general public expound their views on the assumption that the layman can be beguiled into an anæmic interest in the discoveries of scientific workers, if first convinced that nothing he learns will be likely to compel him to revise a neolithic ideology. With the elder Huxley, Mr Crowther holds that scientific progress is most interesting to the layman when, and because, it does challenge his complacency.

This sadly old-fashioned tradition, upheld in the recent broadcast addresses of Prof Levy, has only one other surviving representative in Great Britain. In the Soviet Union it is taken for granted. Perhaps his frequent visits to Russia in recent years have hardened Mr Crowther in the archaic conviction that science does not require a coating of saccharine mysticism to establish its cultural credentials.

Mr Crowther's latest book is in the form of an itinerary. If for this reason it is, conventionally speaking, without form, it is certainly not void. It is a mine of intimate and painstaking observation, annotated with copious statistics, embellished with a minimum of propaganda for or against the political practice of the Soviet regime. The bulk of the material is based on a visit to Moscow and Leningrad during 1931, when he accompanied the Principal of the Manchester College of Technology, Mr Mouat Jones, who was invited by the Supreme Economic Council to discuss with them problems of technical education. Technical education is an issue of vital importance to the success of the Five Year Plan, on account of the shortage of highly trained technical workers in a country which has previously lagged behind western Europe in the development of urban industry.

Perhaps the outstanding difference between the present tendency of higher education in the Soviet Union as contrasted with western institutions is specialisation. Courses of theology, anthropology, psychoanalysis, and biophysics do not appear side by side in the calendar of a single institution.

"Soviet technical colleges have been organised on the monotechnic principle. Polytechnics have been dissolved into groups of monotechmics, which probably helps to explain the extraordinary number of colleges with courses of university standard. There are monotechmics for turbine engineering, for building, for margarine manufacture, for central power station engineering, etc. Each college is run in close connexion with some factory, the students gaining shop experience in the factory, and sometimes the factory staff doing some teaching in the college. The relations between the college and the factory with which it is associated are organic and not casual."

One of the grave defects of educational progress in America and western Europe is prodigal expenditure on buildings destined to outlive the usefulness of their design. A guiding principle in the development of the monotechnic policy is the concentration of technical institutes in suitable situations, where associated industries are concentrated. Since the Soviet Union anticipates

immense changes in the localisation of industry, expenditure on buildings is kept at a minimum. The claims of adequate equipment come first.

"There is much lavish equipment. We saw at least two college laboratories better equipped than anything of the kind in Britain, these were for artificial silk technology and machine tools. The exterior of buildings is often deceptive. One may go up to an old building whose outer walls are peeling and surrounded by appalling bogs of mud, walk into the entrance hall through crazy swing doors into filthy corridors, and enter a spotless laboratory shining with distemper and light, and fitted with the latest apparatus."

In Great Britain a similar policy of development carried out under present conditions would entail a considerable restriction on the choice of available students. Doubtless this consideration has reinforced other factors tending to strengthen our own policy of founding new provincial universities with inferior equipment in mushroom-like profusion. The Soviets have met this difficulty in their own way. Technical students are paid wages by the State.

"As the student is not economically dependent on his parents he can afford to ignore their probably conservative tendencies. As his living is guaranteed he can live anywhere in Russia, at the most convenient place. In Britain we take the colleges to the student to save his parents and himself trouble and expense, in Russia the student receives a wage and is as mobile as a journeyman artisan."

The number of higher technical institutions in the Soviet Union is expanding with remarkable rapidity under the impetus of the enthusiasms which the Five Year Plan has engendered. Of the higher technical institutions with courses of university rank Mr Crowther states

"there are 188 of them in existence in U S S R, though doubtless they vary in standard and degree of development. The population of U S S R is 160,000,000, so there is approximately one technical high school to each million of the population. The various institutes and parts of institutes in the British Empire, including India, which might be considered as parallel to the U S S R technical high schools, total perhaps 240, for a population of 500,000,000, i.e., one to about every 2,000,000 of the population. The figure 240 is arrived at by counting up the number of universities and university colleges and multiplying by three to allow for the multiplication made by the subdivision of polytechnics into monotechmics in U S S R. It is almost certainly unduly favourable to the British Empire, but helps to express the proportion."

An integral part of the policy of Soviet technical education is to link the forces of productive work

with the system of instruction at every stage. Of special interest in this connexion are the *Rabfacs* and branches of the Central Institute of Labour.

"The Rabfacs, or 'workers' faculties', are a system of secondary schools for adults of 18-30 years of age. They prepare intelligent workers for admission to the technical high schools. There are 321 of them, and those we saw seemed good and filled with earnest students, some recently demobilized from the Red Army and still in their uniforms. Only the three R's are required for entry, students are expected to leave after four years with a knowledge higher than matriculation standard. These institutes are the product of the backwardness of elementary education and the nature of social organisation. The Central Institute of Labour, or CIT, gives six-month courses on manual operations. The courses have been worked out scientifically on the time-and-motion principles made familiar by Owen, Taylor, Ford, and others. The Russians have evolved their own system. They say a raw worker can become as skilled in six months by this training as he would in four years' casual work as an artisan's mate in the shops. They propose to put 700,000 workers through such courses in 1931."

It is not surprising to learn that the Russians have their own way of meeting the claim that a 'liberal' education fits the student to take an interest in the government of the country. "Besides his technical studies, the student has to do much social work. He must attend heavy courses in political science in which he learns the philosophy of communism and the ideas of Marx and Lenin."

Judging from the syllabuses of the qualifying examinations (p 55 *et seq*) for entrance to the higher technical schools—especially those in mathematics and physics—the teaching of Marx and Lenin does not exert any appreciable influence on the teaching of science at present. The requirements of materialist examiners seem to be substantially identical with those of examiners in western universities where the official philosophical point of view is idealistic. Pure mathematicians will be reassured and experimental educationists will be disappointed to learn that there is little evidence of any attempt to link the teaching of elementary mathematics with the practice of the workshop or to break away from the tradition of formalism which we ourselves have inherited from classical idealism.

According to Mr Crowther there is immense enthusiasm among the students. Their enthusiasm is instructive in its bearing upon the place of competition in a scientifically planned economy.

"Many of the students we saw were more enthusiastic than any groups of students we had seen

anywhere else in the world. Perhaps they were enthusiastic for technical education because life in Soviet Russia offers so few luxurious distractions. Interest in work is stimulated by competitions between the students of institutes. Two institutes sign an agreement to compete with each other in academical prowess. We attended an impressive ceremony for the signing of the agreement for one of these 'Socialist competitions' as they are called."

### The Study of the Soil

*Soil Conditions and Plant Growth* By Sir E John Russell (Rothamsted Monographs on Agricultural Science) Sixth edition Pp viii + 636 + 7 plates (London, New York and Toronto: Longmans, Green and Co, Ltd, 1932) 21s net

IT is difficult to realise to-day how recent is the study of the soil as an entity. The earliest contributors to what was later to develop into soil science regarded the soil almost as an inert vehicle for the supply of some active principle essential to plant growth. For van Helmont this principle was water, for Glauber saltpetre, and for Kulbel a product of the organic matter. At the end of the seventeenth century, Woodward, it is true, had shown that both soil and water are alike essential for plant growth, but that air is also a necessity was not demonstrated until the classical researches of Hales in 1731. It was not until the early part of the nineteenth century that Humphry Davy, and later Schubler, stressed the importance of the physical properties of the soil. By the middle of the nineteenth century the controversy between Unger and Thurmann, *inter alia*, as to whether the physical or chemical properties of the soil are the more important for plant life, served to stimulate further inquiry into the needs of plants.

The complexity of the physical and chemical problems involved was not, however, adumbrated until van Bemmelen demonstrated the colloidal properties of the soil, in 1878, and Way, in 1850, the phenomenon of double decomposition, leading in recent times to the researches of Knop, Gedroiz, and Hissink on exchangeable bases. In the late 'seventies, Schloesing, Muntz, and Warrington were laying the foundations of soil bacteriology, but yet it is perhaps true to say that, whilst up to the end of the nineteenth century many investigators had utilised the soil as a medium for analytical research, the synthetic concept was almost entirely lacking. With the present century came a definite recognition of the interdependence of the various soil conditions and the importance of their interaction for plant life.

The work at the Rothamsted Station by a co-ordinated team of investigators, first under Sir Daniel Hall and since 1912 under Sir John Russell, epitomises the changed method of inquiry into soil problems, and though the actual synthesis of a soil eludes us, the synthetic attitude of mind has in no small degree mitigated the evils of analytical abstraction

The successive editions of the work before us, from the slim volume of 1912 to the present robust tome of nearly four times the size, constitute a record of the development of soil science in relation to plant growth during this modern period. The last quarter of a century has not only witnessed detailed investigation of the organic population of the soil at Rothamsted, initiated as the result of Russell and Hutchinson's classical researches on partial sterilisation of the soil, but, also, the studies of plant ecologists, which emphasised the properties of natural soils and their correlations with plant successions, inevitably led to the recognition that the soil is a dynamic and not a merely static complex. Owing to the continued action of climatic and biotic factors, a soil can thus pass from an immature to a mature condition.

One of the most important additions in this volume treats of this dynamic aspect, and deals with the changes which the composition of the soil undergoes and the climatic classification of soil types. Here the inclusion of the results of Russian investigators will be the more welcome from the relative inaccessibility of some of the original publications. The two chapters dealing with the soil in Nature, of which the first is concerned with the changes in mineral composition and the second with the changes in the organic matter, replace the former chapters on the chemical and physical relationships of the soil and the carbon and nitrogen cycles. The essentials of the previous text are retained, but the new form with additional matter extends to a further thirty-two pages. The general character of the work, which remains unaltered, is too well known to require indication, whilst the smaller additions throughout are too numerous to specify. It must therefore suffice to say that the present edition has been brought thoroughly up to date, and is consequently even more indispensable than heretofore as a handbook alike for the agriculturist, the botanist, or indeed anyone interested in the problems concerned with the complex relations between plants and the medium in which they grow.

E J SALISBURY

### Short Reviews

*Engineering Geology* By Prof H Ries and Prof. Thomas L. Watson. Fourth edition. Pp vii + 708. (New York: John Wiley and Sons, Inc., London: Chapman and Hall, Ltd., 1931) 25s net.

THE appearance of a fourth edition of Ries and Watson's "Engineering Geology" is an indication of continued appreciation of a useful work which covers a good deal of ground and provides the civil engineering student, for whom it is intended, with a very fair and reasonably adequate survey of the manifold aspects of the subject. Written by professors of geology attached to two universities (Cornell and Virginia) in the United States, the basis of illustration is mainly North American and, for that reason, may be none the less attractive to the European student, as widening the range of his knowledge. The photographic views are excellently reproduced, and the diagrams generally are very clear and distinct, as also is the text. There is, however, an unfortunate omission of a decimal point in a table on page 446 *l*, and the index, though fairly full, is not helpful in tracing information—about permissible foundation pressures, for example.

In a manual of this kind, which touches on a great variety of matters germane to the subject in varying degrees, it would be easy to make carping criticisms as to omissions and inadequacies of treatment. Mining, quarrying, tunnelling, water supply, building, embankment, harbour work, and road construction are all engineering operations requiring a knowledge of geology, and 700 pages do not provide any excess of space for so extensive a purview. Probably, here and there, some fuller treatment might be felt desirable, but, on the whole, it will be admitted that it would be difficult to compile a textbook on lines to which unqualified agreement could be secured. The authors avow that their aim throughout has been to emphasise the practical application of geology to engineering work, and it is in regard to this practical side that the book will make its most effective appeal.

B C

*The Examination of Fragmental Rocks* By Prof F G Tickell. Pp x + 127 + 12 plates. (Stanford University, Calif: Stanford University Press, London: Oxford University Press, 1931) 25s net.

THE physical examination of rocks and their component minerals, with which this book deals, forms part of many technical investigations. Among the substances which may profitably be tested by methods here described are sedimentary rocks in geological studies, particularly in connexion with oil geology, building stones, sands intended for specific industrial purposes, raw materials for the ceramic industry, and soils. Prof Tickell has incorporated in his manual those methods of investigation which are likely to be of common interest and utility. The treatment presupposes a knowledge of scientific fundamentals.

The first part of the book describes methods for the size analysis of grains, and for the determination of the porosity and permeability of rocks. This is succeeded by a chapter dealing with the preparation of samples for optical examination. A knowledge of optical mineralogy is not assumed, and in Chap. v full instructions are given for the identification of minerals by their optical properties, with the aid of the petrographic microscope. The treatment here is practical rather than theoretical, being aided by explanatory plates and diagrams. The book concludes with a descriptive list of minerals commonly occurring in sedimentary rocks, a determinative table of the non-opaque minerals of the same group (unfortunately printed in such small type as to hinder rapid reference), and a bibliography. In view of the varied materials to which the practical methods elaborated may be applied, these latter three sections are not perhaps so exhaustive as might be desired. The value of the book, however, lies in its description of laboratory methods, and for this purpose it can be recommended.

*High Speed Steel* By Marcus A. Grossmann and Edgar C. Bain. Pp. ix+178. (New York: John Wiley and Sons, Inc., London: Chapman and Hall, Ltd., 1931) 17s. 6d. net.

THE practical importance of the high-speed steels in the engineering industry, coupled with their interest from the metallographic point of view, renders any account of these materials of wide appeal. English readers should perhaps be warned that, so far as the manufacture is concerned, the treatment of this applies specifically to American practice, which for many reasons would not be followed in its entirety by producers in Great Britain. It is of interest, for example, that the authors do not even mention the use of the induction furnace as a melting appliance for such alloys. Further, except for special purposes, smaller ingots would be cast here than apparently are usual in America. These smaller ingots are less subject to serious heterogeneity than larger masses would be, but of necessity result in a considerable reduction in the amount of work which can be put upon them.

The second section of the book is devoted to an account of the properties and metallographic characteristics of the alloys. A quite considerable amount of information has been concentrated into these pages, and on the whole the existing state of knowledge is fairly summarised. The position is such, however, that differences of opinion are not surprising. Most metallographers would hesitate to be quite so dogmatic as the authors on many points regarding, for example, the exact composition of the constituents which occur in these steels, or respecting the exact function of each of the elements which are present. The work is, however, of considerable interest and value, it deals with a most complex alloy system, and if, from its very nature, it emphasises the necessity for further research of a definitely fundamental type, it will perform a still more useful purpose.

F. C. T.

*Recent Advances in Microscopy Biological Applications* Edited by Dr A. Piney. Medicine, by Dr A. Piney, The Living Eye, by Basil Graves, Zoology, by Dr E. W. MacBride and H. R. Hewer, Botany, by E. C. Barton-Wright. Pp. vii+260. (London: J. and A. Churchill, 1931) 12s. 6d.

THE four chapters within the covers of this book are so diverse in their subject matter—and even more in their method—that it seems scarcely worth while to make them into a volume. The chapter on the microscopy of the living eye, though written with expert knowledge, stands apart from any field in which the others might be included. The first chapter is essentially a short account of recent advances in human histology, but is entirely undocumented. The last two chapters purport to deal respectively with animal and plant cytology. The former chapter, however, deals almost entirely with the cytoplasm. The reason given for practically omitting attention to the nucleus is that the cytologist's work in this field is "practically at a close" since the general correlation of Mendelian laws with chromosome behaviour. This view leaves out of account the recent work on nuclear structure. The chapter gives, however, a very good survey of investigations on such cytoplasmic structures as Golgi apparatus and mitochondria, which will be found very useful for reference. The last chapter is too limited in outlook to be of much value, although much of the material included is of extreme interest, if adequately presented and discussed.

*Patterns for Eight Simple Relief Models illustrating Geological Structures* Designed by Dr Frank Smithson. (London: Thomas Murby and Co.; New York: D. Van Nostrand Co., Inc., 1930) Patterns, 5s. 6d., Cards specially suitable for mounting the patterns, 3s. 6d., Models made-up, uncoloured, 45s., Models made-up, hand-coloured, 63s.

THE patterns prepared by Dr. Smithson are printed in black and white on paper of excellent quality for taking water-colour and varnish. The models they are destined to form differ from those previously issued in that they illustrate the relation between surface relief and outcrop. The structures illustrated are as follows: 1, escarpment with tilted strata; 2, hills and valley with horizontal beds; 3, beds dipping up a valley; 4 and 5, beds dipping down valleys, sloping respectively at angles more and less than the dip (these two models placed together give a valley inlier); 6 and 7, folded beds with axes running respectively across and parallel to the valleys; 8, unconformity. Full instructions for making the models, with an illustration and description of each model, are included. When made up, the models are three or four inches high on a base ranging from 6 in.  $\times$  4½ in. to 6 in.  $\times$  9 in. They may be strengthened by coating with size and varnish. The models are clear and simple, and should prove valuable as an aid to the elementary student in understanding geological maps.

### The Zoological Survey of India \*

By Lieut.-Col R B SEYMOUR SEWELL, I M S, Director, Zoological Survey of India

IN the year 1784 the Asiatic Society of Bengal or, as it was then called, the Asiatick Society, was founded by Sir William Jones. The formation of a Museum was not definitely stated to be one of the objects of the Society, but specimens were frequently sent to the Society, either for examination and report or for safe custody, and in 1796 a definite proposal for the erection of a suitable building, to house the collections that had thus accrued, was first mooted. It was, however, not until 1808 that the Society came to possess its own building, which it still occupies to-day, but from then on definite efforts were made to establish a Museum and this was finally achieved in 1814.

Although Sir William Jones, the founder, was opposed to the collection of zoological objects, on the ground that it entailed the destruction of life, there was, nevertheless, from the very inception of the Museum a quite definite biological bias. At the outset the Museum was subdivided into two parts, (a) comprising archæology, ethnology, and technical exhibits, and (b) including geology and zoology. The former section was placed under the care of the Society's librarian, and the latter under a special curator, the first to be appointed being Dr Nathaniel Wallich, who presented to the Museum duplicate specimens from his own collection in order to form a nucleus.

Up to 1836 the Museum was supported entirely from the funds of the Society, but in that year, owing to financial troubles and losses, consequent on one of the Calcutta banks closing its doors, the Society was compelled to petition the East India Company for assistance in maintaining the Museum and the necessary staff, and in 1839 the Company sanctioned a grant of Rs 300 per mensem for this purpose. The first curator to be appointed under the changed conditions was Dr J T Pearson of the Bengal Medical Service, thus commencing the close association between the Museum and the Government medical services that has continued to the present time. The continual growth of the collections in due time again caused a strain on the Society's resources, and in 1856 the Government of India was petitioned to found an Imperial Museum for India, the outbreak of the Indian Mutiny caused matters to be postponed for a few years, but in 1862 the Government announced its intention of founding such a Museum in Calcutta, and by the Indian Museum Act of 1866 definitely provided for its establishment and created a Board of Trustees for its management. The actual construction of the building naturally took some time, and it was not until 1875 that the Museum was ready for occupation, and the first two galleries, namely, those of archæology and the mammalia, were thrown open to the public in 1878.

A study of the records of the Society shows that during these early years a number of distinguished zoologists had contributed to the collections, and

among these one may perhaps mention Dr J Anderson, who had made two collecting expeditions into Yunnan and China, in 1868 and 1875, and later became the first curator of the Indian Museum. Various other collections came from regions so far apart as Abyssinia, Persia, Tibet, different parts of India, Assam, and Burma, and in addition the Society received very valuable collections that had been made during the Persian Boundary Commission (1870-72), the second Yarkand Mission (1873-74), and the Dafia Expedition (1874-75). All these collections were handed over by the Asiatic Society to the Indian Museum to form the nucleus of the zoological collections.

The next stage in the evolution of the Zoological Survey of India may be said to have begun in 1875 with the opening of the Indian Museum as a State museum, and the appointment of a permanent staff, entirely maintained by funds provided by the Government of India. During the preceding few years the Asiatic Society had been taking a very keen interest in the schemes that were being put forward in other parts of the world for the investigation of the deep-sea fauna, and it felt that India should also play its part in these investigations, the Government was at this time considering the formation of a Marine Survey of India, and in consequence of the representations made by the Society it determined to appoint to this survey a special officer, the surgeon-naturalist, whose duty it would be to carry on investigations on the Indian deep-sea fauna, at the same time ruling that the collections thus made should be the property of the Asiatic Society of Bengal and, after identification, should be incorporated in the collections of the Indian Museum. The first appointment to the post of surgeon-naturalist to the Marine Survey of India was made in 1875, and in 1881 the Royal Indian Marine Survey ship *Investigator* was launched.

At its inception the Indian Museum included sections dealing with zoology, geology, and archæology, and it was not until twelve years later, in 1887, that the section of art and economics was added. From the very commencement the importance of the zoological section was clearly recognised, and this is shown by the fact that the first three appointments to the staff were given to zoologists, namely curator of the Indian Museum, Dr J Anderson, assistant curator, Mr J Wood-Mason, and first assistant to the curator, Mr G Nevill. A few years later the surgeon-naturalist was given an unofficial status in the Museum by being appointed an honorary assistant. Thus, very soon after its inception, the Museum staff consisted of four zoologists.

With the creation of a permanent staff, and as a result of a breadth of vision and a true appreciation of the value of zoological research that has ever characterised the Trustees of the Indian Museum, it became a recognised part of the function of the

\* Paper read before the Association of British Zoologists, Jan 9, 1932

staff to go out into the field and make their own collections, so as to make a study of the living, just as much as of the preserved, animals, it was thus possible for a number of expeditions to be carried out in various parts of the Indian Empire and even beyond its frontiers, and among the latter regions that were visited, mention may be made of the expeditions by the late Dr N Annandale to the Lake of Tiberias in Palestine, to the Talé Sap in Siam, and to Lake Biwa in Japan. These activities naturally resulted in large accretions to the collections, and during this second period in the history of the Zoological Survey very considerable further additions were made by a succession of surgeon-naturalists on the RIMS *Investigator*, pre-eminent among whom stands Col A Alcock, I.M.S. During this period large additions of valuable collections of both the land and fresh-water fauna were obtained as the result of systematic collecting during certain political and military expeditions, notably during

- (1) The Afghan Delimitation Commission, 1885,
- (2) The Afghan-Baluch Boundary Commission, 1896,
- (3) The Tibet Expedition, 1903-4,
- (4) The Sistan Arbitration Commission, 1903-6, and
- (5) The Abor Expedition, 1911-12

Numerous additions were also presented to the Museum by friends of the department, such as officers of the Geological and Botanical Surveys of India, the Indian Forest Service, and the Indian Medical Service, by planters in various parts of India, and finally, but by no means the least, by the officers of the Hooghly Pilot Service, to whom the Museum owes a very valuable collection of the fauna of the estuarine region at the mouth of the Ganges. Special mention must also be made of the collections made by the officers of the Fishery Department of the Government of Bengal and by the research trawler *Golden Crown* during investigation into the fishery resources of the Bay of Bengal.

Several very valuable collections, such as the de Niceville collection of butterflies, the Dudgeon collection, etc., were also purchased by the Trustees.

The rapid increase in the size of the collections, and the consequent work of the Zoological and Anthropological Section of the Museum, resulted in a gradual increase in the staff, and in 1916 there were four zoologists on the permanent staff of the Museum, and, in addition, attached to the Museum were one unofficial, though paid, worker, the late Mr E Brunetti, and the surgeon-naturalist—the total staff thus being six.

It was in this year, 1916, that the Zoological and Anthropological Section of the Indian Museum was converted by the Government of India into the Zoological Survey of India. The reason of this conversion is not to be found in any change in the duties of the officers of the department, but in the recognition by the Government that the work of the section had been and then was, in all essential features, similar to the work that was being done by the already existing Geological and Botanical

Surveys, and the need of placing the head of the section on an equal footing with the directors of these other Surveys as a fellow-trustee of the Museum and not merely a paid servant of the Trustees.

The ever-increasing work of the Survey has from time to time necessitated the creation of additional appointments, and at the present day the full staff as sanctioned by the Secretary of State should consist of a director, two superintendents, and seven assistant-superintendents, the last addition to the staff being the naturalist to the Marine Survey, a post that was previously always held by an officer of the Indian Medical Service. Up to the present time, however, only seven officers have been appointed, and of these one is an anthropologist. In consequence of the policy of the Government of India to indianise the various services, as many Indians as possible have been selected to fill the various posts as they fell vacant or were sanctioned, and to-day the director is the only European in the Survey, the other six officers being Indian.

The conversion of the Zoological Section of the Museum to a Survey gave official recognition to the view that field-work was one of the most important duties of the department, and it thus became possible to formulate definite programmes of work that could be spread over a series of years. A commencement on definite survey lines had, however, been begun some years previously by investigations into the lake fauna of Asia, and this had culminated in the survey of the Chilka Lake, a special volume of the *Memoirs of the Indian Museum* being devoted to the results. The first definite survey of the newly created Zoological Survey was undertaken at the request of the medical authorities in India, who, as the War of 1914-18 drew to its close, became anxious lest the disease schistosomiasis, that was unknown in human beings in India, though present in other animals, might be introduced by troops returning from areas overseas in which this disease is rampant. Systematic investigations were, therefore, undertaken in order to discover whether any of the known mollusc hosts of the Schistosome might be present in India, or, alternatively, whether any of the more common fresh-water molluscs could act as such a host, and, in addition, to determine what species of Cercariæ were already living in the country. As a result of these inquiries, the Zoological Survey was able to inform the Government that, so far as it was possible to judge, there was no fear of an extension of this disease into India, a conclusion that was entirely justified by results, for although the troops from overseas were brought back to India without any precautions whatsoever being taken in the way of quarantine, there has been no spread of this disease in that country.

Our knowledge of the fauna of India is still very incomplete, and in every case in which an officer of the Zoological Survey of India has taken up the study of a group in the animal kingdom it has proved to be necessary that he should first pay careful attention to the taxonomic side, in order

to determine the various species that are present. As a result, considerable progress has been made on these lines, and during the sixteen years that the Survey has been in existence the number of new species that have been described and of 'types' that have been added to the collections of the Indian Museum has averaged some one hundred and twenty-five a year. Up to quite recent times the Survey has not attempted to deal with purely economic problems, unless specially requested to do so, it was rightly considered to be of more importance that their energies should be devoted to purely scientific research, for no zoological research can have any economic value unless it has a scientific basis, and the foundation of all such work is taxonomy. Nevertheless, the Survey has from time to time contributed towards the elucidation of problems of economic importance, and has been consulted by various local governments on such problems as the reorganisation of fishery departments, the institution of biological stations, the preservation of the fauna—as, for example, the Monitor lizards that were being exterminated for the supply of skins for the leather market—oyster fisheries, or the control of various species of animals that were directly or indirectly destroying crops. Within the last two years the Survey has by circumstances been compelled to take up one problem of economic importance, namely, the maintenance and preservation of the *Trochus* and *Turbo* fisheries in the Andaman Islands.

For many years past, each officer has been encouraged to take up two lines of study—one taxonomic and the other general, they are thus brought into touch with some of the wider problems of zoology and are in a better position to take advantage of their opportunities for study in the field, while the department as a whole is in a sound position to undertake team-work and thus to tackle the investigation of any of the more general problems, on the solution of which so much may depend in a country like India, in which agriculture and public health are the two subjects of greatest importance.

The Zoological Survey of India publishes the results of its research work in two serials that are devoted to zoology, namely, the *Records* and *Memoirs of the Indian Museum*, and within the

last year has commenced a third, entitled *Anthropological Bulletins from the Laboratory of the Zoological Survey of India*. These publications are very largely composed of original papers by the officers of the Survey, and by a system of exchanges with some three hundred other societies and institutions the Survey is able with comparatively little cost to maintain a very fairly complete and up-to-date library, that without any doubt is the finest zoological library for purposes of research in Asia. This library is at the service of every *bona fide* zoologist throughout the whole of India, a list is kept of all those who are engaged in research work, and every such worker is allowed to have from the library two volumes at a time for a period of a fortnight. In this way workers are able to keep in touch with and consult recent literature, without which it would be impossible for them to carry on their researches. Within the limits imposed on it by space, the Zoological Survey of India also provides accommodation for any research worker who wishes to come to the Museum in order to carry on his work either in the library or in the laboratory, and there is an ever-increasing demand for facilities of this nature, not only from zoologists in India but also from other countries.

It is no exaggeration to say that if the Zoological Survey is in the future to be curtailed, either in its personnel or its financial resources, to such an extent that the continuance of its publications is rendered impossible, such a blow will be dealt to the study of zoology in the whole of India that it will put the country back to where it was in 1875, when the Museum was first started, and will render almost impossible the satisfactory or trustworthy investigation of every problem in which zoology may be concerned. Finally, any drastic reduction of the staff must seriously endanger the collections. Such collections, especially in a tropical climate, require constant attention for their preservation and continuous study and research to maintain them in an up-to-date and scientific condition, so that each animal is correctly labelled and can at once be referred to for comparison and examination, and if in the future these collections are allowed to decay, the loss, not to India alone but to the whole world, will be one of the first magnitude.

### Steel in Building Construction

IT is usual to criticise methods of engineering design by calling the engineer's 'factor of safety' a factor of ignorance. In one sense the accusation is true, since the factor is a cover for uncertainties, but, in effect, it is a concise expression of experience and, properly used, is as legitimate as the apparently more rigorous processes in calculation. It is an inheritance. The efforts of progressive engineers are bent towards its improvement. They attempt the reduction of its margins by enlargement of data, perfection of analysis, and advancement of materials. Sometimes a greater precision in things understood leads to a reduction of the factor, only to disclose

the increased importance of things less well understood, and thereby to compel a return. The subject of fatigue in materials and the history of the development of high speed machinery provide numerous examples.

It can scarcely be denied, however, that the factor of safety is subject to serious misuse at times. Weak design methods are frequently characterised by a meticulous arithmetical accuracy in inadequate calculation, covered by an arbitrary factor that may make the design quite safe but certainly renders the careful arithmetic ludicrous. Possibly this charge of imperfect calculation and arbitrary safety factors could be

laid against building structure design. At least, building codes vary so widely that there would appear to be justification for the belief that they reflect a very variable standard in the comprehension of data and of method.

The confusion created by varying codes, in conjunction with a feeling that the full value is not being derived from the use of steel in building structures, and that the highly advanced technique of modern steel structural work is not being fully exploited, has led to a general recognition that comprehensive and systematic investigation is required to obtain precise information and thereby facilitate the establishment of economical design and more uniform regulations. While the recognition of the necessity is widespread, it is gratifying to find that the Department of Scientific and Industrial Research in Great Britain has taken first and bold steps towards this end. The first report, now issued, by the Steel Structures Research Committee,\* set up by the Department in 1929, shows that a wide view has been taken of the task, and that an ambitious programme of research has been undertaken.

The Committee was appointed to review present methods and regulations for the design of steel structures, and to investigate the application of modern theory to such design with a view towards its improvement by the establishment and definition of the data and processes required. The remit would have been more concise and equally comprehensive if it had called for an investigation of all aspects of the 'factor of safety' in steel building structures. The connexion of theory and practice is essentially implied in 'factor of safety'. The factor of safety may be nominally modified by extended theory without compelling any important alteration in practice. Theory may advance in completeness, but practice can only be modified by research.

The Committee has very completely realised the true interrelations of established practice, advanced theory, and experimental research, and the programme of work reflects this clearly. But, while understanding the necessity of conducting a full survey of existing methods as a guide to research developments, it has been assumed that the nature of the essential problems would not be greatly altered by the examination of a multiplicity of design systems, while research progress would certainly be impeded. The division of the main lines of work is therefore of the order of an 'intelligent anticipation' of the requirements, and the Committee has decided upon schemes that embrace such leading items as floor loads, building strains, stress analysis, materials, welded connexions, and building vibration. Good progress appears to have been made with all of these except the last, which, under modern conditions, may ultimately present a restrictive influence on the easy development of more economical design.

The enormous amount of detail work described in the report forbids even a summarised mention

within this space, but the interest of technical structural engineers will be aroused by the design and tests of the new 'micrometer-microscope' strain gauge and the proposed use of such gauges on the five-story framing of the new Geological Museum at South Kensington, to obtain results for the unloaded frame and as the floors are progressively loaded. There are also most interesting test results on the buckling of I-beam webs, following a request by the British Steelwork Association to have the question of web stiffness examined. In a section on materials, Prof. A. Robertson presents the results of an investigation on the use of small turned specimens in steel testing. These display distinct differences when compared with the yield point results for large flat specimens.

Structural steel framing is of an apparently simple rectangular form, but requires an elaborate theoretical development for its stress analysis. The theory is usually based on the assumption that the joints are rigid. This is not actually the case. The report deals with the general theoretical case of non-rigid connexions briefly, but it is clear that all questions of slip and flexibility at joints require extensive experimental work, as well as theoretical investigation. Both theory and experiment have been employed for riveted, bolted, and welded connexions by Prof. C. Batho, whose results and views are given in a lengthy section of the report.

Laboratory tests on joints alone, however, can scarcely promise to give conclusive information. In actual framing, the mysteries of eccentric loading accompany those of joint flexibility. Calculations given in the report with different assumptions as to eccentricity and joint rigidity show remarkable differences. This appears to have prompted the design of a full scale, three-story, experimental frame which has been erected at the Building Research Station and is to be subjected to extensive experiment when loaded by water tanks. This is perhaps the most notable of the Committee's efforts, and represents an exceptional step in structural research.

A full scale experimental research is always impressive but is, unfortunately, seldom comprehensive. The natural desire is, therefore, to extract the most from the expensive large-size equipment and to endeavour to generalise by the aid of model investigations. The recent American research on arch dams is an excellent example of this procedure. The Committee has also model work in hand, which includes the Beggs deformeter method with celluloid models, and slope measurement methods with others. It is to be hoped that the joint conditions in rectangular framing will not prove too much for small scale models.

The last section of the publication is preceded by the report of the panel dealing with the welding of steel structures, which describes tests of welded joints and outlines a future programme of research upon this mode of construction. Welded connexions are not yet widely adopted and a great deal of investigation will probably be necessary before they become generally acceptable, but

\* Department of Scientific and Industrial Research. First Report of the Steel Structures Research Committee. Pp. xii + 276 + 11 plates. (London: H.M. Stationery Office, 1931.) 5s. net.

they offer many advantages, and more precise knowledge and methods of control may overcome the hesitancy of responsible authorities

The first and last sections of the report are widely apart in position and closely related in theme. The first—which includes in one place an account of a most interesting survey of the real loads on office floors—presents the results of a comparative examination of the regulations controlling steel frame building construction in Great Britain, the Dominions, and in some foreign countries. The general comparison of regulations displays extraordinary variations in such matters as floor loads and wind pressure allowances, and in the clauses governing the proportioning of members. On practically every page of this section there is evidence of the confusion and variety

that can be introduced by autocratic authorities at work independently

The last part presents the recommendations of the Committee for a code of practice governing the general use of structural steel. In view of the fact that these recommendations accompany a first progress report, there is always the probability of future amendment in the light of subsequent data. It is understood, however, that the code will be explicitly referred to in the model by-laws to be issued by the Ministry of Health. This may be taken as an augury of the full recognition that will be accorded the completed work of so influential and representative a Committee, the first report of which displays a breadth of vision and power of planning that promises ultimate success in a difficult task.

### Obituary

PROF P N KRYLOFF

THE name of Porfiri Nikitich Kryloff, professor of botany and plant geography at the University of Tomsk, who died on Dec. 27, 1931, at the age of eighty-one years, will always be associated with the exploration of the Siberian flora. Born of a poor family, Kryloff had to earn his living ever since he left his school, still a boy in his teens. Becoming an apprentice in a chemist's shop at Perm, young Kryloff became seriously interested in chemistry and medicinal plants, and devoted his spare time to studying for an examination to obtain a pharmacist's degree at the University of Kazan, and to the collection of plants. After obtaining the degree, he continued to work as a dispensing chemist.

The botanical exploration of the Perm province and of the Ural Mountains was now Kryloff's main and only recreation. With very limited resources, often on foot, he wandered over that enormous area, and produced a series of papers on its flora, which was then very little known. In 1874 it became possible for Kryloff to abandon his old profession and to devote himself entirely to botany, by taking a modest appointment as a 'learned gardener' at the University of Kazan. While at Kazan, he made an extensive study of the flora of that province, but dreamed of botanical explorations in wider and less-known regions.

At the foundation of the new University of Tomsk, the first scientific centre in Siberia, Kryloff did not hesitate to take there the same post of 'learned gardener', becoming later the keeper of the botanical museum, which he built up himself. A new, and practically virgin, field was now open before Kryloff, and he threw himself into this congenial task with his usual energy. Most of western Siberia, the Altai Mountains, and northern Mongolia offered an inexhaustible supply of most interesting problems in the systematics and distribution of plants. An enormous herbarium, comprising more than 200,000 specimens of plants, was the result of the journeys of Kryloff himself and of his students, who were attracted by his

unaffected and enthusiastic love of Nature. In systematic studies in the herbarium Kryloff was as thorough as in collecting. He prepared detailed descriptions of all the species known to occur in the regions visited, and maps showing areas of their distribution elsewhere. This formed the basis of his well-known 'Flora of Altai and of the Tomsk Province', published in seven volumes between 1901 and 1914. The importance of this work for the study of the flora of temperate Asia and even of Europe cannot be overestimated, and it is not surprising that it was soon out of print.

In 1913 Kryloff was invited to take the post of botanist in charge of the Siberian herbarium at the Academy of Sciences in St. Petersburg but the economic difficulties of living in the capital during the revolution induced him to return in 1917 to Tomsk, where he became professor of botany. Here he set himself a new and a very ambitious task of preparing a complete flora of western Siberia, from the Urals to the Yenisei and from the Arctic Ocean to central Asia. It may seem almost unbelievable, but the work was completed, with the usual masterfulness, within six years, after which several years were spent in endless efforts to find the funds for its publication. It was only in 1926 that the great 'Flora of Western Siberia' began to come out in parts, and is still continuing to be published.

Prof. Kryloff's interests were not purely floristic, but mainly phytogeographical, and his exceptional first-hand knowledge of Siberia and its plants enabled him to produce a series of most valuable papers on the distribution and past history of the Siberian flora. One of the points particularly well brought out by Kryloff's work was the existence in the Altai Mountains of an ancient centre of the origin of many typical Siberian plants, which later migrated widely and reached European countries. The foundation of a large and very prolific school of Siberian botanists should be considered amongst the most important achievements of this self-made pioneer of botanical exploration of Siberia.

## MR J J JOICEY

MR JAMES JOHN JOICEY, who died early in March, aged sixty-one years, was the founder of the Hill Museum and also a munificent benefactor of the Natural History Museum, South Kensington.

Mr Joicey started to form a collection of British butterflies and moths at quite an early age, but it was not until his interest in exotics was aroused that there appeared much likelihood of his adding appreciably to the sum of human knowledge. In 1910 he acquired the collection formed by Henley Grose-Smith, an ardent disciple of W C Hewitson, and two years later added to it the Herbert Druce collection. These two collections, both rich in type material from all parts of the world, were so extensive that extra accommodation had to be built to house them. The Hill Museum was thus established in 1913. Through the exertions of collectors employed by Mr Joicey from this time onwards, remarkable collections were sent home to him from Peru, the Amazon valley, Dutch New Guinea, Waigeu, the Schouten Islands, many other of the less-known islands of the Dutch East Indies, Yunnan, Hainan, and Central Africa. All these were rich in new material, or shed light upon the geographical distribution of the Lepidoptera.

The scientific results were published from time to time in various journals, but mainly, from 1921 onwards, in the *Bulletin of the Hill Museum*, which, during its eleven years' existence, has run to four handsome and richly illustrated volumes, to which, no doubt, would have been added many others had not Mr Joicey's enthusiasm for his subject outrun his ability to meet the expenses. Between 1914 and 1930 about sixty papers by Mr Joicey, in collaboration with others, were listed in the titles in the "Zoological Record."

Besides employing collectors, Mr Joicey acquired by purchase many valuable collections, notably those of Roland Trimen, H J Elwes, Col Swinhoe, Hamilton Druce, Wichgraf, Ruffarth, and others, all rich in types. A catalogue of the type specimens of Rhopalocera in the Hill Museum had just been completed, and all arrangements made for its publication, a few days before Mr Joicey's death. This, better than anything else, will indicate the value of the contents of the Hill Museum, at least from a taxonomic point of view, the total number of type specimens enumerated is 2724. In the moths, the types were probably even more numerous relatively, as they had been worked fairly thoroughly by many specialists, but as they have not been catalogued, it is not possible to give definite information. Two years ago it was estimated that Mr Joicey's museum contained approximately four hundred thousand specimens, including about five thousand types, but for some years prior to that, large sections of it, with which it was found impossible to cope at Witley, had been presented to the British Museum (Natural History) from time to time with results highly beneficial to the remaining collection, in that the staff under Mr Talbot's capable direction was able to maintain it in really excellent order and thoroughly up to date throughout.

The closing of the Hill Museum and the disbanding of its staff are events which will have serious repercussions throughout the ranks of lepidopterists in all parts of the world, and will definitely slow up the rate of advance in this much favoured though, we fear, often despised branch of science.

In addition to his intense keenness on butterflies and moths, Mr Joicey had a wide general interest in natural history, was an excellent game shot, an enthusiastic fisherman, and a very successful amateur gardener. His collection of orchids contained many rarities and had brought him quite a number of prizes.

## SIR WILLIAM SMITH

SIR WILLIAM ROBERT SMITH, who died suddenly on March 17, aged eighty-two years, commenced his career at the age of fifteen years as assistant to a chemist, but so well did he use his opportunities that he was able to enter the medical school of St Bartholomew's Hospital and later to complete his medical studies at Edinburgh, where he obtained the double qualification of the Colleges in 1871. He afterwards graduated M D at Aberdeen and D Sc in public health at Edinburgh, and became a barrister-at-law. He was keenly interested in politics—contesting some of the Scottish university seats—and in academic and civic life.

It was in the domain of public health that William Smith made his mark. He was for several years medical officer to the old School Board for London and director of the public health laboratories in King's College, London. He afterwards became professor of forensic medicine in King's College and Hospital Medical School, succeeding the late Sir David Ferrier in this office, and found time to edit the seventh edition of Guy and Ferrier's standard textbook of forensic medicine. He was a member for many years, and vice-chairman 1910-13, of the old Metropolitan Asylums Board.

William Smith will be remembered for his insistence that a special diploma in public health should be a necessary qualification for the medical officer of health of the larger districts, and the institution of the diploma in public health was largely owing to his efforts. For many years he had been principal of the Royal Institute of Public Health, of which he was the virtual founder, and only recently had completed a scheme for the removal of the Institute to a new site in Queen's Square, and had just lived to see the erection of the skeleton of the new building there. He was a good speaker and able controversialist, and the congresses of the Royal Institute of Public Health at home and abroad owed much of their success to his great capacity as an organiser. R T H

WE regret to announce the death, at the age of eighty-four years, on March 25, of Prof Rushton Parker, professor of surgery in University College and the University of Liverpool since 1882. Prof Parker practised and taught surgery since 1869, and was among the first to practise Lister's system of antiseptic surgery. For many years he was consulting surgeon to the Liverpool Royal Infirmary and Bootle General Hospital.

## News and Views

## Centenary of James Wimshurst

AMONG the best-known inventors of electrical machines of the last part of the nineteenth century was James Wimshurst, the centenary of whose birth occurs on April 13. The son of Henry Wimshurst (1804–84), the constructor of the pioneer screw-propelled ship *Archimedes*, Wimshurst was born at Poplar, and after leaving school was apprenticed at the Thames Iron Works, Blackwall, then a well-known shipbuilding yard. At the age of twenty-one years he became a ship surveyor to Lloyd's Register, from 1865 until 1874 was chief of the Liverpool Underwriters' Registry, and then for twenty-five years, 1874–99, was chief shipwright surveyor to the Board of Trade in London. Living at Clapham, he had a good private workshop and for twenty years devoted himself to the improvement and construction of electrical influence machines. The early machines of this type had all sprung from Volta's electrophorus and had been built by Lichtenberg, Bennet, Cavallo, Nicholson, and others, but it was not until the work of Topley (1836–1912) and Holtz and Wimshurst that there was any marked advance in design. The machine with radial strips of tinfoil and contact brushes was described by Holtz in 1881 and again in 1882 and 1883 by Wimshurst, whose improvements were made independently. Altogether he made more than ninety Wimshurst machines. Many of these were presented to hospitals, and two of his very large ones are preserved in the Science Museum. A member of the Physical and Röntgen Societies, and a manager of the Royal Institution, Wimshurst was elected a fellow of the Royal Society in 1898. He died suddenly on Jan. 3, 1903.

## The Asiatic Society of Bengal

THE Asiatic Society of Bengal held its 148th annual meeting in its rooms at No. 1 Park Street, Calcutta, on Feb. 1—one of its patrons, Sir Stanley Jackson, the Governor of Bengal, being in the chair. In the unavoidable absence of the president, Lieut.-Colonel R. B. Seymour Sewell, the presidential address was delivered by the senior vice-president, Dr. U. N. Brahmachari. In the address, attention was directed to the proposals put forward by the Government of India for extensive retrenchment in the various scientific services in India, many of which owe their inception to the Society, and in the Indian Museum, in which the Society takes particular interest, since the nucleus around which the Museum has been built up consisted of the Society's own collections that were handed over for safe custody to the Government in 1875. By the terms of the Indian Museum Act of 1910 these collections and all additions thereto, except those purchased afterwards by the trustees of the Museum, must, if the trust ever be terminated, be returned to the Society. It was emphasised that the maintenance of the scientific services is essential for the economic development of India, and that, whereas scientific research is one of the most profitable in-

vestments that a government can make, a country that neglects the scientific investigation of its natural resources pays, in the long run, very heavily for its neglect.

THE membership of the Asiatic Society of Bengal shows a decrease during the past three years, largely consequent on the present unsettled state of India. Among the losses that the Society has suffered during the last year by death, we notice the names of three fellows, among them the great scholar Maha Mahopadhyaya Dr. Haraprasad Shastri, who was elected to a fellowship in 1910, and five members, one of whom, Mr. James Peddie, met his death by assassination at the hands of the revolutionary party in Bengal. The fall of membership, combined with the present financial depression, has caused the Society anxiety regarding the continuance in the future of its activities, and has emphasised the need of creating and building up reserve funds for such objects as the rebuilding of the Society's premises, their present house having been built in 1808 on land granted to them by the Government in 1804, and for the endowment of the Library, which, by its continual expansion, of necessity imposes a steadily increasing strain on the Society's resources. It is a matter of some surprise to learn that in all the 148 years of its existence, and in view of all that the Society has in the past done for India, no financial benefaction of importance has ever been given to it—a state of affairs that reflects very unfavourably on India when contrasted with the support given to similar societies in other civilised (and especially western or American) countries.

## Meteorology in India

A PESSIMISTIC note is sounded in the opening passages of Dr. C. W. B. Normand's recently issued "Report on the Administration of the Meteorological Department of the Government of India in 1930–31." This report, which is dated Sept. 11, 1931, has to record a set-back in the rapid expansion of the Indian meteorological service outlined in the corresponding report of last year. The expansion was due to the legitimate demands of aviation, the set-back to the equally legitimate demands of financial stringency arising from the world's economic blizzard. Dr. Normand states that the schemes connected with aviation had in the year under review reached a stage of completion, but many schemes, some not connected with aviation, have had to be shelved. One scheme that is apparently to proceed unchecked is connected with the development of a special branch of the department to deal with the problems of agricultural meteorology. This practically originated in the Report of the Royal Commission on Agriculture in 1928. It contemplates both statistical and experimental studies, the standardisation of the meteorological and physical data collected at experimental farms, the development and standardisation of methods of measuring radiation, evaporation, soil temperature, and so on,

and the determination of the local weather and climate appropriate to each crop. It is proposed to employ two agricultural meteorologists and subordinate staff for a preliminary period of five years, at an annual cost of Rs 40,000. The necessary grant has been made by the Imperial Council of Agricultural Research.

#### The Musk Rat in Europe

Two exhibition cases have recently been placed in the Central Hall at the Natural History Museum, South Kensington, immediately facing the visitor on entering the building, in order to inform the public what kind of animal the musk rat, *Ondatra zibethica*, Linn., is, how it lives, and the damage it does. Better known as musquash, the musk rat has been for many years of considerable commercial value because of its fur, which is very beautiful, being thick, soft, richly coloured, and glossy. Naturally an inhabitant of North America, it has been imported to Europe by misguided people who thought some advantage and profit might result from this step. The experiment provides yet another illustration of the serious danger involved in interference with the balance of Nature. In its original home, the musk rat's increase is controlled by the usual kind of checks, which do not exist or have not developed elsewhere. It is said that in 1905 two males and five females were turned loose in Bohemia, twenty-one years later, in 1926, there were computed to be no fewer than a hundred millions of these animals in Central Europe. Owing to their burrowing habits, the damage that they do to waterways is enormous, and great expense has to be incurred in checking them. In Great Britain the danger has been recognised, and under the Destructive Imported Animals Act, 1932, regulations, which come into force on May 1, have been formulated to control the distribution of the musk rat in this country.

#### Destruction of Rats

IN addition to the British Museum pamphlet on rats, noticed in NATURE for Dec 19, 1931, p 1036, two others have recently appeared. All deal with the specific characters and the natural history of the black and the brown rat, and with the methods of destroying rats or preventing their ingress, so that there is a considerable amount of overlapping, but each pamphlet has its own particular points of excellence. The Ministry of Agriculture and Fisheries *Bulletin*, No 30 (price 6d net), repeats in new and much more attractive form the old *Miscellaneous Publication* on rats, and its object is to supply practical information leading to rat-destruction. The second pamphlet, by Colin Matheson, deals with "The Brown and the Black Rat in Wales" (National Museum of Wales, price 6d net), and discusses some very interesting facts bearing upon the occurrence of rats and the rat menace in the Principality. It is surprising to learn that in the years 1922-28 inclusive the rat-catcher in the Port Sanitary Area of Cardiff destroyed of black rats, by far the more rare of the two species in Britain at the present day,

22,036 from ships and 3072 from dock warehouses, and of the brown rat, only 50 and 266 in these areas respectively. But the proportions change as the docks recede, for in Cardiff City, from March 1928 until February 1930, only 78 black rats were caught, as against 1961 brown rats. The menace of such great numbers of the plague-distributing black rat in the Port area is one which the author does well to emphasise.

#### Implements from the Oldoway Beds

FOUR original implements and casts of eleven others from the Oldoway beds in Tanganyika have been presented to the British Museum by Dr L S B Leakey on behalf of the East African Archaeological Expedition, and are to be exhibited without delay at the top of the main staircase in the prehistoric section of the Department of British and Mediæval Antiquities. They come from the following beds, beginning at the base. Bed No 1, associated with *Dainotherium*, a predecessor of the elephant and generally assigned to the Miocene pre-Chelles types. Bed No 2, lower part, with *Hipparion* and *Elephas antiquus* early Chelles types. Bed No 2, upper part, the horizon of Prof Reck's Oldoway man, with *Hipparion*, *Elephas antiquus*, and *Hippopotamus gorgops* late Chelles types. Bed No 3, with fauna as Bed No 2 transition Chelles to St Acheul. Bed No 4, lower part, with *Elephas antiquus*, *Hipparion*, *Hippopotamus gorgops*, *Pelorovis* and extinct antelopes early St Acheul types. Bed No 4, upper part, with same fauna as lower advanced St Acheul types.

#### Japanese Plants in the Netherlands

THE Leyden Branch of the Royal Horticultural Society of the Netherlands, in order to commemorate the founding of the well-known acclimatisation garden for Japanese plants by Dr P F von Siebold, is planning to hold an exhibition, on May 4-8, at Leyden, of living Japanese plants, shrubs, and trees, many of which are descendants of plants imported by von Siebold. Belgian and Dutch horticulturists are collaborating to make this collection as complete as possible. At various other institutes of the University of Leyden, smaller exhibits will be held of the ethnographical, zoological, and botanical material gathered by von Siebold. Biographical materials will be shown in the University Print Collection. In the University gardens, which still contain more than forty of von Siebold's trees and shrubs, a bronze statue, by the sculptor, O Wenckebach, will be unveiled by the grandson of von Siebold and by the grandson of his head-gardener.

#### Von Siebold and the "Flora Japonica"

PHILIPP FRANZ VON SIEBOLD was born at Wurzburg on Feb 17, 1796. He studied at his home university, where he received his doctorate in medicine in 1820. In 1823 he arrived at Decima, Japan, as a military doctor, but he also devoted himself to the natural history, medicine, ethnology, ethnography, and history of Japan. At Nagasaki he founded a medical school and clinic, but for political reasons some of his ever-increasing botanical, zoological,

mineralogical, and geological collections were confiscated by the Japanese authorities in 1828, fortunately, not long before he had sent many specimens to Leyden. He also sent a living tea plant to Java, thus originating tea culture on that island. In 1827, Siebold published a small catalogue of Japanese economic plants. On Dec 30, 1829, political unrest was so acute that he was ordered to leave Japan, and he then settled in Holland. He met the German singer, J. J. Hoffmann, who was also a linguist. In 1845, Hoffmann published a description of Siebold's books, manuscripts, and maps which he had brought from Japan. Zuccarini, the Munich botanist, helped with the classification of botanical material. Publication of the "Flora Japonica" was begun in 1835 and continued until 1842, but after Zuccarini's death, von Siebold discontinued further publication and the materials became the property of the Government Herbarium at Leyden, where the Von Siebold Collection is still visited and consulted by botanists. Von Siebold's influence on horticulture was even greater. His imported specimens formed a nucleus for horticulture in Belgium and Holland, but the original "Jardin d'Acclimatisation Nippon" no longer exists. His zoological collections are preserved in the Museum of Natural History at Leyden and his ethnographical material at the Leyden Ethnographical Museum. Von Siebold died at Munich on Oct 18, 1866.

#### Decline of Australian Parrakeets

THE re-discovery of a species supposed to have become extinct is especially a matter of congratulation when it has some particular claim to interest, as is the case with the splendid grass-parrakeet (*Neophema splendida*), of which a pair has recently reached England as a present to H.M. The King. Mr D. Seth-Smith, in commenting on this in the *Avicultural Magazine* for January (p. 36), mentions that a few captured specimens had appeared in Adelaide, and that, always rare, the species, which is found in south and south-western Australia, had completely disappeared for about sixty years, and was supposed to be extinct, until a specimen occurred at Koonibba, crippled by collision with a wire fence. The special interest of the species lies in the very brilliant colouring of the male, which has a blue face and wing-patches, a scarlet breast, and yellow abdomen, contrasting with the green of the upper surface, the female has no red and is generally duller. The length is about eight inches. A whole group of small grass-seed-eating Australian parrakeets like this appears to be on the decline, common species like the turquoise (*N. pulchella*) suffering as well as this rare one. Fortunately, like so many Australian birds, they are free breeders in captivity, and may possibly be preserved if domesticated as the budgerigar has been.

#### False Mimicry in Animals

THE short-tailed South American monkeys known as uakaris are never common in captivity, so it is as well to direct attention to the recent acquisition of a specimen of the red uakari (*Cacajao rubicundus*) by the Zoological Society of London, which exhibits it in

the Tropical House along with some more familiar American monkeys. The resemblance of this species to an orang-utan in miniature is noticeable, and is paralleled in the Bird House next door by a specimen of the South American magpie tanager (*Cissopis leveriana*), which exhibits an equally striking resemblance in miniature to the magpie. Other more striking examples could be given, in both mammals and birds, of this false mimicry, or resemblance between creatures which do not inhabit the same region, when size as well as general appearance correspond. In the Bird House may also be seen an example of Chaulet's Cissa (*Cissa hypoleuca Chauleti*), which will be interesting to watch, as, like the better-known Indian species (*C. sinensis*), this green bird changes into blue without a moult, the change taking place by a gradual alteration of tint, which reminds one of the fading into blue of green paint.

#### A Direct Reading Optical Micrometer

A MICROSCOPE for measuring small lengths has recently been put on the market by Messrs W. Ottway and Co., Ltd., Orion Works, Ealing, W.5. The microscope, which gives a magnification of 25, is about 6.5 cm. long and is mounted on a small tripod. Focusing is effected by sliding the microscope tube through the holder, fine adjustment being made by rotating a milled ring on the stand. Measurements are obtained by a direct reading of a scale on a graticule fitted into the microscope, a screw focusing adjustment being provided to bring the graticule into the focal plane of the eyepiece. Scales reading to 0.01 mm. or 0.001 mm. are supplied and are easily interchangeable. The instrument can conveniently be used as a linen counter, or for the measurement of Brinell impressions or of small objects up to 0.1 mm. in length. For measurements of length up to 10 mm. an alternative objective, fitted with a 0.1 mm. scale and giving a magnification of 15, is obtainable. As the graticules may be ruled to any desired scale or pattern, the micrometer should prove useful as a test instrument in many industrial operations. It can easily be applied, for example, to the testing of screw threads, a graticule with the required thread form being used. Its compactness and the ease and speed with which readings may be made are additional advantages.

#### Performance of Gears

IN a paper by Messrs Hyde, Tomlinson, and Allan, of the National Physical Laboratory, read before the Institution of Automobile Engineers on April 4, an interesting account was given of researches which have been in progress at the Laboratory during the past few years on the performance of gears. The best gears are made of special alloy steels, either air or oil hardened, and afterwards finished to an accuracy of a few ten-thousandths of an inch by grinding. The work of the Laboratory shows that such gears can transmit power with the very high efficiency of more than 99 per cent. At the high speeds of rotation to which gears are subjected, a tooth out of its true position by less than a thousandth of an inch may come into mesh with a shock sufficient to double or

treble the normal pressure on the tooth. Although it has ample strength to withstand this augmented pressure as a steady load, if the effect is repeated often enough the metal becomes fatigued, and the tooth may ultimately break off as a result of this fatigue. Thus the fatigue strength should be the criterion employed in design, rather than the more usual considerations of static strength and durability. The experiments further showed that this type of gear can be run under load for many millions of revolutions with scarcely any appreciable wear of the tooth faces, presupposing the best conditions of lubrication. It appears as though the lubricating oil, when functioning efficiently, almost completely holds the steel surfaces apart by a highly tenacious film. Another feature of interest is that even ideally perfect gears must lose some of their running perfection when it is necessary for them to transmit power under heavy loads. This is due to the small elastic bending of the teeth caused by the heavy load, which has the effect of disturbing the perfect uniformity of the motion which the gear would otherwise transmit.

#### Earthing Radio Sets

IN the wiring rules issued by the Institution of Electrical Engineers, it is recommended that every radio-receiving set actuated by electric power taken from the public supply mains should be effectively earthed at certain specified points. The obvious way of doing this is to connect these points by conductors with a water pipe. According to the *Wireless World* for March 23, the Metropolitan Water Board has been investigating to find out whether the leakage currents flowing into their mains are producing appreciable corrosion in the mains or are eating them away at the places where the currents leave them to enter the earth. In the early days of tramway electric traction, where the current when it left the motors was supposed to get back to the generators by the tram rails, it was found that a large proportion of the current left the rails and came back by the earth, the water and gas pipes, and other conductors. In several cases damage was done to the pipes. To obviate this trouble, the Board of Trade insisted that the voltage drop between any two points on the rails should not exceed seven volts, and this has proved satisfactory. If it is found that the leakage currents are damaging the water or gas pipes, we have no doubt that some remedy will soon be invented, as electrical engineers have been making an intensive study of the problem of 'earthing' for several years. It would be very difficult to prove that the damage, if any, is being done by the mains-driven radio sets, as the currents in the earth are well known to be mainly due to cosmical and atmospheric action and to the leakage or 'vagabond' currents from electric supply stations.

#### Large Alternators

It is gratifying to find from the *Metropolitan Vickers Gazette* for January that, despite depression in many industrial centres, rapid progress was made during last year in engineering development.

Two turbo-alternators have been supplied to the power station at Clarence Dock, Liverpool, each of which has a power of 71,500 kilovolt-amperes, runs at 1500 revolutions per minute, and generates at 7250 volts. One of the two large 80,000 kilovolt-ampere machines for the new Battersea Power Station of the London Power Company is now practically completed. This is the largest 1500 r.p.m. machine yet built in Great Britain. The company has also built a 40,000 kva alternator for the Victoria Falls Power Company, two of 31,250 kva capacity for Japan, and several for Australia, Mexico, and Calcutta, all of these large machines run at the almost incredible speed of fifty revolutions per second. Three novel and interesting motor-alternator sets have been supplied for operating the Sperry gyroscope equipments on the Italian liner *Conte di Savoia*. The replacement of human effort by automatic electric control is proceeding very rapidly. The steam pressure in the boilers is maintained at the desired value by automatic regulation of the fans and grates. Substations are sometimes left entirely unattended, the starting, synchronising, and stopping of 14,000 kva alternators being entirely automatic. The first section of the power station the company is building for Montevideo is now operating. It is interesting to note that the whole of the work from the commencement of the excavation of the site to the starting up of the plant was carried through in sixteen months. This performance is excellent considering the distance the bulk of material had to be shipped.

#### Science Talks by Gramophone

SCIENCE teaching in schools in the United States is to be enlivened by the employment of gramophones for bringing to the class-rooms the voices of the most eminent men of science. The records are being produced by Science Service, of Washington, D.C. The "Durium" record used consists of a thin layer of a synthetic resin so strong that the sound grooves can be placed very close together, nearly doubling the time of playing. We have received a set of the first seven records, and listened to them with pleasure. The recording has been excellently done, and each speaker gives the kind of talk that would be expected from him were he invited by a teacher to address a class for five minutes. The speakers in this first set are Prof. Robert A. Millikan, director of the Norman Bridge Physics Laboratory, California Institute, Pasadena, on "The Rise of Physics", Prof. John C. Merriam, president of the Carnegie Institution, Washington, on "The Record of the Rocks", Prof. Edwin G. Conklin, professor of zoology in Princeton University, on "The Mystery of Life", Prof. Karl T. Compton, president of the Massachusetts Institute of Technology, on "Science and Engineering", Prof. L. H. Baekeland, pioneer in industrial chemistry, on "Chemistry and Civilization", Prof. William H. Welch, professor of the history of medicine in Johns Hopkins University, on "The Tubercle Bacillus", and Dr. William M. Mann, director of the National Zoological Park of the Smithsonian Institution, Washington, on "Our Animal Friends". With each record is supplied a card,

bearing on one side a photograph of the speaker and on the other side bibliographical details of his scientific work, together with the complete text of the talk. The set is being offered at an inclusive charge of three dollars, and, at such a low price, may be recommended not only to teachers and students, but also to anyone interested in science in general

#### Co-ordination of Scientific Terminology

AMONG the scientific questions which the International Institute of Intellectual Co-operation has been asked to examine is the co-ordination of scientific terminology. Various international organisations, including the Commission of Electro-technics and certain scientific unions, have undertaken, each in its respective sphere, the compilation of scientific or technical vocabularies. The different branches of science, however, constantly employ, and very often with a different meaning, terms which are common to all of them. It therefore appeared indispensable that the co-ordination of these terms should be undertaken. For this purpose, a Committee recently met at the International Institute of Intellectual Co-operation. It was composed of Prof Cabrera (Madrid, chairman), Prof Cotton (Paris), representing the International Union of Physics, Prof Willstatter (Munich), Prof Lowry (Cambridge), delegates of the International Union of Chemistry, Prof Selys-Longchamps and Dr Ledoux (Brussels), representing the International Union of Biological Sciences, and Prof Lombardi (Rome), delegate of the International Union of Electro-technics. The Committee invited the International Institute of Intellectual Co-operation to undertake the work of co-ordination in conjunction with the international organisations concerned.

#### Fourteenth International Physiological Congress

THE Fourteenth International Physiological Congress will be held in Rome on Aug. 28–Sept. 3, as arranged, no change has taken place in the date fixed for it. The president of the Congress is Prof Bottazzi of Naples, and the International Committee consists of Profs Pavlov (Russia), Johansson (Sweden), Howell (United States), Frank (Germany), Lapicque (France), and A V Hill (Great Britain). The inaugural ceremony will be held in the Grulo Cesare Hall of the Campidoglio. The inaugural lecture will be given by Prof A V Hill, and receptions will be given by the Governor of Rome and the Royal Academy of Italy. Foreign participants in the Congress will enjoy a reduction of fifty per cent for tickets taken, under certain conditions, on the Italian railways. In the near future, those who have already returned their applications for membership will receive further information, and a programme of the inaugural ceremony and other functions.

#### Announcements

It is announced in *Science* of March 18 that Sir James Jeans has been made an honorary member of the Washington Academy of Sciences, in recognition of his contributions to the dynamical theory of gases, to cosmogony, and to astrophysics.

THE William H. Nichols Medal for 1932 of the New York Section of the American Chemical Society was presented on March 1 to Prof J. B. Conant, chairman of the division of chemistry in Harvard University, in recognition of his work in organic chemistry, particularly in the chemistry of chlorophyll.

At the annual general meeting of the Physical Society, held on March 18, the following officers were elected: *President*, Prof A. O. Rankine, *Secretaries*, Dr Ezer Griffiths (Business), Dr Allan Ferguson (Papers), *Foreign Secretary*, Prof O. W. Richardson, *Treasurer*, Mr R. S. Whipple, *Librarian*, Dr J. H. Brinkworth.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned—A male assistant in the Department of Printed Books of the National Library of Wales—The Librarian, National Library of Wales, Aberystwyth (April 12). A registrar of the Wigan and District Mining and Technical College—The Principal, Wigan and District Mining and Technical College, Wigan (April 15). A director of education for the City of Sheffield—The Director of Education, Leopold Street, Sheffield (April 16). A Dickinson research travelling scholar in medicine, a Dickinson research surgery scholar, and a Dickinson research scholar in medicine, each at the Manchester Royal Infirmary—The Secretary to the Trustees, Royal Infirmary, Manchester (April 16). A head of the Commerce Department of the Wigan and District Mining and Technical College—The Principal, Wigan and District Mining and Technical College, Wigan (April 18). A full-time lecturer with degree, and a knowledge of general engineering or mining, at the County Technical Institute, Worksop—The Principal, County Technical Institute, Worksop (April 21). A junior scientific officer in an Admiralty establishment at Portsmouth—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W. 1 (April 23). Probationary assistant naval constructors—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W. 1 (April 30). An assistant in the Department of Forestry of the University College of North Wales—The Registrar, University College of North Wales, Bangor (May 9). A professor of physiology at the London Hospital Medical College—The Academic Registrar, University of London, South Kensington, S.W. 7 (May 14). A head of the Mechanical and Electrical Engineering Department of the Harris Institute, Preston—The Principal, Harris Institute, Preston (June 1). An assistant lecturer in civil engineering, building construction and sanitary science at the Battersea Polytechnic—The Principal, Battersea Polytechnic, S.W. 11. An assistant master for elementary engineering and metalwork at the Sawston Village College—The Education Secretary, County Hall, Cambridge. A temporary junior assistant with first or second class honours in physics, or equivalent, at the Experimental Station, Porton, near Salisbury—The Chief Superintendent, Chemical Defence Research Department, War Office, 14 Grosvenor Gardens, S.W. 1.

### Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### Palæacariformes, a New Sub-order of the Acari

THE discovery of the two genera of Acari for which it has been necessary to create this new sub-order affords us ample evidence of the truth of the contention that our knowledge of the teeming world of microarthropods is as yet very insufficient. A thorough exploration of the fauna of the tropics by the use of the modern method of automatic collecting, devised by the late Prof. Antonio Berlese of Florence, will undoubtedly yield a rich crop of many new and strange forms which will substantially alter our conceptions regarding these creatures.

One of the genera for which the new sub-order had to be erected, *Archeonothrus*, was discovered by me in 1905 in Natal, and a brief preliminary description of it was published in 1906,<sup>1</sup> the name implying that it was considered related to the Oribatid genus, *Nothrus*, although more primitive. The re-examination of this form last autumn, following on an investigation of the mouth-parts of the Oribatids,<sup>2</sup> revealed, however, at once such a large number of differing features that it soon became evident that the genus could not possibly be referred to any of the existing sub-orders of Acari. At the same time I was convinced that *Archeonothrus* must be considered the most primitive of recent Acari, presenting as it does the very aspect of a living fossil the nearest relative of which must be sought for amongst the fossil Acari from the Devonian epoch.

This discovery was eclipsed by the later surprising discovery of yet another genus of the new sub-order, this time in the soil in a spruce forest in southern Sweden, a genus which I have called *Palæacarus*.

In their general appearance both forms resemble very much the nymphæ of Oribatids, this very deceptive resemblance being due to the soft cuticle, the presence of pseudostigmatic organs, although of a more primitive type, and the long hairs on the hysterosoma.

The body is divided into two parts, the propodosoma and the hysterosoma, between which there is a distinct neck-shaped constriction. The propodosoma is covered by a shield which has five pairs of hairs besides the pseudostigmatic organs. Such a large number of propodosomatic hairs is very unusual in the recent Acari, but occurs also in the Devonian *Protacarus* described by Stanley Hirst from the Old Red Sandstone, a feature which lends support to the view held by some acaridologists that the propodosoma consists of six segments besides the acron.

The isolated position as well as the primitive organisation of the Palæacariformes is most clearly realised when one examines their maxillæ. In these there is no trace of the so-called hypostome which is such a conspicuous feature in the Oribatids, but, on the other hand, there are two pairs of appendages, the lateral ones of which are evidently homologous with the so-called maxillary lobes of the Oribatids and the Mesostigmata, while the median appendages are conspicuous through the presence of three pairs of hairs. In the Oribatids the maxillary lobes are enormously developed and meet in the middle, thus completely concealing the median appendages, the presence of which had previously been completely overlooked, but which I was able to discover by dissecting these organs, once the presence of them in the Palæacari-

formes had rendered it likely that they occurred also in the Oribatids. As regards the presence of two pairs of maxillary appendages, the Palæacariformes agree with the most primitive Trombidiformes, for example, *Speleorchestes*.

The new sub-order is undoubtedly related to the most primitive Oribatids. Thus the shape of the chela of the mandible, as well as the easily recognisable content of the hind part of the alimentary canal, is a sufficient proof that they are phytophagous, feeding probably on decaying leaves or possibly on mosses and lichens. But from the Oribatids they differ profoundly in the absence of hypostome and epimera and still more by the respiratory organs, which consist of a pair of minute stigmata on the base of the mandibles exteriorly and short tracheæ.

It is on the whole evident that the Palæacariformes show affinity to the more primitive forms of both the Oribatid and the Trombidiformes. The genus *Protacarus* mentioned above was placed by Hirst amongst the Eupodidæ, which are, however, in my opinion too specialised to be taken into account. As a matter of fact, *Protacarus* agrees in many respects in a striking way with the Palæacariformes, especially *Palæacarus*, as, for example, in the number of hairs on the propodosoma, the presence of pseudostigmatic organs, and, although Hirst could not discern clearly the shape of the chela of the mandible, he describes it as dark-coloured, which is precisely the colour of the chela of the phytophagous Oribatids and of *Palæacarus*.

It is admittedly premature to draw any far-reaching conclusions regarding the phylogeny of the Acari from the facts established by the discovery of *Protacarus* and the Palæacariformes, and the very discovery of the latter, however unexpected, must make it seem quite within the bounds of possibility that other forms may yet be discovered, representing new types which will remodel our present conceptions regarding the relationship of the different sub-orders with one another and concerning the origin of the Acari.

Nevertheless, the dim outline of the ancestor of at least the Oribatids, the Tyroglyphids, and the Trombidiformes seems to begin to materialise in the shape of a creature not unlike *Protacarus* and the Palæacariformes, whereas the connexion between these groups and the Mesostigmata and the Holothyrioidea seems very obscure.

#### Function of the Adrenal Medulla

ADRENALINE, as it is generally known to-day, seems to be different from the substance primarily produced by the adrenal gland. Adrenaline appears to be a decomposition product of the natural substance, the decomposition taking place post-mortem in the gland and during subsequent chemical manipulations. If the glands (ox) are collected and the extraction carried out in the usual way, adrenaline is obtained. If, however, the chances for post-mortem enzymic reactions are minimised by rapid excision and cooling of the glands after death, a substance is obtained by careful extraction the physiological action of which is distinctly different from that of the ordinary adrenaline. We propose to call this new substance 'novadrenaline'.

As is known, small doses of common adrenaline, of about 0.001 mgm, given intravenously to the decerebrated or anaesthetised cat, usually produce a fall of blood pressure. Only larger doses cause a definite

rise Novadrenaline does not show this depressor action of small doses. Even doses fifty times smaller give still a definite pressor effect.

If larger doses are given (0.05 mgm. with cut vagi), novadrenaline always produces a higher rise of blood pressure than the corresponding amount of adrenaline, as determined by colorimetric comparison. A striking difference between the actions of the two substances is seen also in the duration of their pressor effects. While with common adrenaline (0.05-0.1 mgm.) the blood pressure, after reaching its maximum, quickly returns to the original level, the rise of blood pressure produced by an equal dose of novadrenaline subsides only very slowly, often with a wide plateau lasting for several minutes, reaching the original level in 8-10 minutes, the return being three to four times slower than with adrenaline. As shown by I. Huszák in this laboratory, the action of novadrenaline on the Trendelenburg frog preparation is much stronger than that of adrenaline.

The difference between the action of adrenaline and that of our extracts cannot be due to the modifying influence of some accompanying substance, since on further purification the action of novadrenaline remains unchanged.

Our extracts were made with  $\frac{1}{2}$  per cent trichloroacetic acid, 2 c.c. being used for every gram of the minced medulla. The suspension was quickly heated to 80° C. and rapidly cooled again. The neutralised extract could be concentrated *in vacuo* to a syrup, and fractionated with methyl alcohol and acetone. From the acetone, novadrenaline was precipitated as a ferrous complex, the formation of which is highly specific for the *ortho* dihydroxy grouping. The active substance was liberated in watery solution from this complex by hydrogen sulphide, and still showed an unchanged activity. If once extracted and kept cool, novadrenaline is reasonably stable.

As to the chemical nature of novadrenaline, no more than a mere suggestion can be given at present. The evidence available suggests that novadrenaline is a low molecular weight ester of adrenaline, the esterifying radicle being attached to the alcoholic hydroxyl of the side-chain. This suggestion is based on the following observations. The general chemical properties of adrenaline and novadrenaline are very similar. The specific activity of novadrenaline can be destroyed by treatment with hydrochloric acid. As shown by the iron colour reaction, the *ortho* dihydroxy grouping is free in novadrenaline, as in adrenaline. Since the entire physiological activity of novadrenaline is destroyed by formaldehyde, the imino group seems also to be free.

As to the physiological importance of novadrenaline, it seems to be not unlikely that this substance presents, with respect to adrenaline, a relation analogous to that of acetylcholine to choline, with an activity related, however, in this instance, to the true sympathetic nervous system.

We hope that our findings may contribute not only to knowledge of the action of sympathetic nerves, but also to the understanding of pathological conditions, such as hypertonia and asthma.

We were led to the finding of novadrenaline by the study of oxidation processes, but were greatly helped in our work by a personal communication from Sir H. H. Dale, relating to a casual observation of the more persistent pressor action of extracts from the adrenal gland, in comparison with that of chemically isolated adrenaline. Our work has been supported by the Ella Sachs Plotz Foundation.

### Gill-Morrell and Barkhausen-Kurz Oscillations

IN NATURE of Feb. 6, Mr. R. Cockburn has described results which appear to show the presence of two types of electronic oscillations in a triode with positive grid voltage.

I should like to express disagreement with this result, for the following reasons.

(1) Mr. Cockburn's results shown in his Fig. 2 have been obtained by the simultaneous variation of two quantities, circuit length and filament emission, and present a misleading picture of the relation between circuit tuning and wave-length.

The apparent overlapping of the so-called Gill-Morrell and Barkhausen-Kurz oscillations is due to the dependence of the space charge oscillation frequency on emission current. Fig. 10 of Hollmann's paper<sup>1</sup> quoted by Mr. Cockburn shows the true nature of this effect.

(2) The variations of wave-length and amplitude with circuit tuning have been satisfactorily explained as 'coupled circuit' effects.<sup>2</sup> The hypothesis of two different types of oscillation is therefore unnecessary.

(3) There appears to be no valid experimental evidence for the existence in gas-free tubes of oscillations independent of the inter-electrode impedances ('B-K' oscillations), and existing theories<sup>3</sup> show that such oscillations are impossible.

(4) The simultaneous existence of two types of oscillation (apart from harmonics) has, so far as I am aware, never been demonstrated. I have shown elsewhere<sup>4</sup> that apparent experimental evidence<sup>1</sup> of this is untrustworthy.

Regarding the effect of varying the emission current, theory and experiment<sup>2</sup> have shown that the oscillation amplitude is a maximum in the region of the transition from space charge to emission saturation of the grid current characteristic. The presence of more than one optimum value of emission current usually indicates the presence of 'harmonic' space charge oscillations,<sup>5</sup> that is, oscillations of frequency nearly, but not necessarily exactly, an integral number of times that given by the Barkhausen-Kurz equation. 'Overtones' is possibly a better name than 'harmonics' for these oscillations.

It is probable that such oscillations occurred in the cases mentioned by Mr. Cockburn. The fact that the wave-length was shorter at the lower emission value (which is the opposite of the normal result where only fundamental oscillations are concerned) favours this hypothesis.

E. C. S. MEGAW

Research Laboratories of the  
General Electric Company, Ltd.,  
Wembley, Feb. 11.

<sup>1</sup> Hollmann, *Ann. Phys.*, **86**, 129, 1928.

<sup>2</sup> Tank and Schiltknecht, *Helvetica Phys. Acta*, **1**, 110, 1928.

<sup>3</sup> See, for example, Möller, *Jahrb. drahtl. Tel.*, **34**, 201, 1929.

<sup>4</sup> Paper to appear shortly, probably in *Jour. I. E. E.*

<sup>5</sup> Potapenko, *Z. tech. Phys.*, **10**, 542, 1929.

In my original letter (NATURE, Feb. 6), only the actual fact of the existence of two types of oscillations was mentioned, with perhaps insufficient explanation. In view of Mr. Megaw's letter, however, I feel that more details should be given.

Mr. Megaw explains the results as due to the variation of space charge oscillation frequency with emission current, suggesting, presumably, that a maximum in the amplitude of the oscillations would be obtained quite normally when this frequency corresponds to that of the external circuit. Perhaps it was not made sufficiently clear that the ranges of emission current for the two types of oscillations are quite distinct.

For example, with  $V_g = 40$  v,  $V_a = 0$  v, the space

charge saturation current is in the neighbourhood of 20 ma. The optimum emission for the maintenance of the 130 cm Barkhausen-Kurz wave is fairly constant at 16 ma for variations of the tuning circuit, except at points A (Fig 2, previous letter), where it drops to 14 ma, corresponding to the drop in wave-length noticeable at these points. In the Barkhausen-Kurz zone, therefore, the oscillations are a maximum in the neighbourhood of space charge saturation of the grid current characteristic, in agreement with the results of Tank and Schiltknecht mentioned by Mr Megaw. The secondary optimum emission value maintaining approximately the same wave-length is 8 ma. The emission range for optimum maintenance

FIG 1—Variation of plate current (and wave-length) with emission current

of the Gill-Morrell oscillations is continuous from 1 ma to 11 ma, the wave-lengths extending from 90 cm to 170 cm. The emission for optimum maintenance of a wave-length of 130 cm in this zone is 3 ma.

With the tuning bridge fixed in such a position as to offer a wave-length suitable for maintenance in the Gill-Morrell zone and variation of emission current, usually a sudden change in plate current, together with a change in wave-length, is noticed as the oscillations change from one type to the other. A clear example is shown in Fig 1.

It is not at present possible to offer a full explanation of the existence of the two zones. However, it has been shown<sup>1</sup> that electron oscillations can occur in the grid-anode space when it is space charge saturated, and in the valve used the dimensions were such as to permit this state to exist. If, then, oscillations can occur in the anode-cathode space as well, there would appear to be sufficient justification for postulating the existence of two types of oscillations. Fundamentally, no doubt, they are due to the same basic cause, and if in his forthcoming paper Mr Megaw co-ordinates the various conflicting experimental results, a distinct advance will have been made.

#### Light as a Factor in Sexual Periodicity

REFERRING to the recent papers and communications of Dr J. R. Baker and Mr R. M. Ranson and Prof T. H. Bissonette, read before the Royal Society, Feb 4, Dr Marshall<sup>1</sup> suggests that the conclusion concerning light as a factor governing sexual periodicity involves a principle of wide application.

No 3258, Vol 129]

In view of this remark, it may be of some general interest to biologists to know that so far as the flowering plants are concerned this holds true.

Since a brief account of the earlier work on these lines was published in 1924,<sup>2</sup> further investigations have been carried out, and more than one hundred varieties and species have now been tested in Great Britain, whilst in America, Russia, and elsewhere similar work has been done. The results have appeared in various botanical periodicals.

Briefly, it appears that the period of light exercises a profound influence upon the habit of growth, and determines whether many plants flower or remain in the vegetative condition. Under an unfavourable period of light, the formation of sexual organs may be suppressed for very long periods during which vegetative growth continues (Garner and Allard). The flowering plant is so organised morphologically that the response can be strictly localised to one part (Knott). The distribution of the sexual organs in the plant may also be controlled in another manner, as, for example, in hemp, where 'sex reversal' may occur, or in cucumber, where the sex ratio may be modified as a result of the influence of the period of light (Schaffner).

All observers record that the utilisation of the food products, whether in storage or in rapid growth, reflects the operation of this factor, which may also govern the rate of tuber formation (Maximov).

I am unaware that much information has as yet been collected from studies made with cryptogams. However, in the Hepaticæ (Liverworts) the formation of sexual organs and their supporting tissues is at least partially controlled by this factor (Wann).

Possibly the well-known periodicity of the plankton (diatoms, peridneans, and crustaceans) would also provide an interesting series of observations when studied under varying conditions of light and constant temperature, salinity, etc. M. A. H. TINCKER

<sup>2</sup> M. A. H. Tincker, NATURE, 114, 350, Sept 6, 1924

WITH reference to the letter of Dr F. H. A. Marshall on the above subject,<sup>1</sup> I should like to direct attention to the relation of sexual maturity in marine invertebrates to the phases of the moon, a relation which was stated to exist many years ago and seemed at first scientifically incredible and imaginary, but which has been more recently verified by exact research carried out by several competent marine zoologists. The most famous case is that of the Palolo worm, *Eunice viridis*, the sexually mature posterior parts of which swarm at the surface of the sea off the islands of Samoa and Fiji in the mornings of the seventh, eighth, and ninth days after the full moon of November. The most recent paper on the subject is that by Silvio Ranzi of the Zoological Station of Naples.<sup>2</sup> In many other species of Polychæta the sexual maturity and discharge of mature ova and sperms has been shown to synchronise with particular days of the lunar cycle, but in some localities certain species show no evidence of such a relation.

Ranzi's own researches were made on *Platynereis dumerilii*, in which he found that mature individuals occur at Naples from March to November, but that the greatest number of spawning individuals occurred on the third day after the full moon. Sexual maturity is thus not confined to one lunar month of the year in all cases as in the Palolo, but the sexual cycle is affected by the lunar cycle.

Ranzi concludes that the sexual cycle of marine annelids is influenced by a lunar factor, which cannot be the tide, because it occurs in the Mediterranean, where the tides are negligible, nor the light, because sunlight has no such effect. He suggests, therefore, that the influence of the moon is due to some action of unknown nature, not perceptible to our senses, but producing an effect on the sexual cycle of organisms. The facts would suggest that the effect is due to some peculiarity of moonlight which is absent from sunlight, and here is a question which bio-physicists might investigate. Moonlight is, I believe, polarised, but I do not know that any attempt has been made to test the effect of polarised light on the sexual cycle of living organisms.

### Stomatal Movement and Hydrogen Ion Concentration

In order to test the effect of the hydrogen ion concentration of the cell-sap on stomatal movement, experiments were made with the stomata of *Tulipa*, *Scilla*, *Iris*, and *Tradescantia*. It was found that the hydrogen ion concentration of the cell-sap of the guard-cells was approximately 4.5, while the epidermal cells were slightly less acid. The stripped epidermis was placed in buffer mixtures of known hydrogen ion concentration and left for two, six, twelve, and twenty-four hours respectively. The mixture used was the B. D. H. 'Universal Buffer Mixture'. For each time interval, one set was kept in the light and another in the dark for comparison. It was found that, in the case of *Tulipa*, the stomata were closed between pH 1 and pH 5, and at pH 6, 7, and 9 they were open, the maximum being at pH 7. In the dark the stomata were open at pH 5, 6, 7, and 9, the maximum being at pH 5. In the case of *Scilla*, the closure continued up to pH 6 in light, to pH 5 in the dark, with a maximum at pH 7.

In order to avoid the possibly toxic effects of the buffer mixture, the experiments were repeated with solutions of carbon dioxide, of pH values 4.4, 4.6, 4.8, and 5.0. In all these, the stomata of *Tulipa* were open, the greatest opening being at 4.4 in light and 5.0 in dark. *Scilla* showed closure at pH 4.4 and 5.0 in light and dark, opening at 4.6 and 4.8. *Iris* stomata were open throughout the whole range in light, and closed at 4.8 and 5.0 in dark, with a maximum opening at 4.4. *Tradescantia* showed a maximum opening at 4.4 in light, and closed at 4.4 in dark, with greatest opening at 5.0.

It is evident from this that the stomata of these forms are susceptible to changes in the pH value of the sap produced by carbon dioxide, and that the guard-cells respond by movement to these artificially produced changes. The experiments of which this is a preliminary account are still in progress, and it is intended to extend the observations to dicotyledons as well as to monocotyledons.

### A Virus Disease of Tobacco in South Africa

AN obscure and destructive disease of tobacco has occurred for many years in the Stockenstrom district of the eastern Cape Province. It is becoming yearly more serious, and frequently causes total loss of both seed-beds and early plantings. Recent investigation has shown that it is a virus disease which, although

bearing some resemblance to the 'ring-spot' described by Smith<sup>1</sup> and Wingard,<sup>2</sup> has important distinctive characters of its own.

A constant symptom of the disease is the sudden stoppage of apical growth and the stunting of leaves in process of formation. Leaf-spotting develops along various lines, but is usually of a 'ring-spot' or hieroglyphic type, often definitely related to the veins in a fern-leaf pattern. The youngest leaves show marked distortion and blistering, frequently accompanied by brilliant mottling. General chlorosis is usual in varieties of the Burley type, and is followed by discoloration of the stem in cortex and pith and by root decay associated with secondary organisms. Affected plants either die outright or survive through the season in a stunted condition. Some plants show a partial recovery, and after an interval make new growth from terminal or lateral shoots.

The disease can only very rarely be transmitted by needle puncture, but is readily induced by insertion of a diseased shoot (such as for grafting). It is, however, most easily transmitted by the feeding of a member of the thrips group (*Frankliniella*, species undetermined), and under field conditions this insect appears to be the sole vector. The green aphid common in seed-beds does not transmit the disease.

In the same locality, a tomato disease is prevalent which appears to be identical with the spotted wilt of Australia.<sup>3</sup> Distinctive diseases of *Datura Stramonium*, *Physalis* (two species), and *Nicandra physalodes* also occur in the field and are transmitted by the same insect vector. From cross-inoculation studies in progress, there is every indication that all six diseases are caused by one and the same virus.

### Oviposition of *Telenomus nigrocoxalis* Aschm. (Chalcididae)

*Telenomus nigrocoxalis*, a hymenopterous egg-parasite of the Coconut butterfly in British Guiana (*Brassolis sophorae* L.), was observed under magnification on an egg-mass of the host. After a careful inspection and tapping of the eggs with her antennae, the female decides upon a particular egg and penetrates the shell dorso-laterally with a few strokes of the ovipositor, which is inserted into a minute puncture. The female remains in this position for about four minutes. Now and then a male stops to tap the female on the head and thorax with his antennae.

One female, probably an old one, was unable to extricate her ovipositor and, after about ten minutes in this awkward position, collapsed and lay apparently dead between the eggs. Presently a male happened upon her, and immediately showed the greatest concern for the unfortunate female. His agitated movements in attempting to revive the female and distracted behaviour were quite touching. A speck of water, accidentally left with my brush on an adjacent egg before this incident occurred, was now noticed apparently for the first time. By means of one of his antennae the male applied some of this water to the prostrate female.

This movement was repeated many times, but without great success, for there was no sign of life yet and the ovipositor was still held by the egg. Another male appeared on the scene and immediately took in

the situation. Perhaps he has had a similar task before. He seized the female by the ovipositor and with the help of the other male dragged it out, and walked off quite unconcerned. The female brushed herself and made off in another direction, followed by a grateful male tapping her affectionately with his antennae.

#### Polish on Metals

MR R. C. FRENCH has reported on electron diffraction experiments on polished metal surfaces (copper, silver).<sup>1</sup> The fact that the diffraction rings become more and more diffuse if the surface is carefully polished is, he concludes, an experimental confirmation of Sir George Beilby's theory, which supposes that by careful polishing a metal surface is covered with a thin amorphous layer of the metal as a supercooled liquid. Mr H. Raether, who is working in this laboratory with a diffraction apparatus,<sup>2</sup> has got similar results with polished metals. I do not, however, believe that for the explanation of these results it is necessary to suppose that the size of the crystals which constitute the surface is really altered so very much by the process of polishing. I should like to suggest a simpler explanation. A polycrystalline metal surface which is bombarded with electrons at a grazing angle gives sharp diffraction rings if the surface consists of small lumps which are thin enough to allow the electrons to pass through; this was first shown by Prof G. P. Thomson.<sup>3</sup> The lumps play the rôle of the grating, and if by polishing the metal they are levelled, the resolving power of the gratings is gradually diminished (corresponding to the diminished breadth of the gratings).

The sharpness of the diffraction rings proves nothing, therefore, about the real size of the crystals, but gives definite information of the degree of levelling of the surface. Finally, if at the highest degree of polishing the lumps have wholly disappeared, the diffraction would be a specular reflection on the plane surface of the polycrystalline target. In this case refraction would occur and cause a considerable shift of the interference maxima—which would also be broadened—and probably the vanishing of (111) and (002), however, this seems not to be realised in the present experiments, and requires further investigation.

F. KIRCHNER

Institute for Theoretical Physics,  
Munich, Feb. 5

<sup>1</sup> NATURE, 129, 169, Jan. 30, 1932.

<sup>2</sup> F. Kirchner, *Ann. Phys.*, 11, 741, 1931.

<sup>3</sup> G. P. Thomson, *Proc. Roy. Soc. A*, 128, 650, 1930.

IN connexion with Mr French's work on polished metal surfaces<sup>1</sup> and Prof Kirchner's very interesting suggestion above that diffuse diffraction rings may be due to extreme flatness of the surface rather than to an amorphous state, we should like to mention some results which we have recently obtained.

Surfaces of platinum spluttered on glass have been examined by electron diffraction; they show various patterns, of which one is that given by platinum in its ordinary state. If the platinum is spluttered in oxygen at a voltage not exceeding about 1150 and a pressure of not less than 0.014 mm., the surface is active in promoting the combination of hydrogen and oxygen by catalytic action. Such surfaces show at first diffuse rings very similar to those found by French for polished metals, but after the surface has been used as a catalyst until its activity is lost, these diffuse rings change to the sharp rings characteristic of normal platinum. This change is also produced by heating *in vacuo*.

No 3258, Vol. 129]

It is unlikely that these diffuse rings are due to an extremely flat platinum surface, which one would not expect to be catalytically active, and we find that the change from diffuse to sharp rings is accompanied by an improvement in the specular reflection, suggesting that the surface gets smoother rather than rougher. It seems more likely that the diffuse rings are due to some substance in a state of very fine subdivision, with perhaps inclusions of gas molecules.

#### Non-polar Auroral Light from the Night Sky in the Tropics

IN a previous communication from one of us,<sup>1</sup> it was stated that the brightness of the auroral green line in the northern and southern night skies at Poona (lat. 18° 31' N) does not show the midnight maximum observed by Lord Rayleigh and by McLennan and his collaborators in temperate latitudes. Further estimates of intensity obtained by exposing Mimosa extreme orthochromatic plates through suitable green and orange filters, and with an aperture of about 45° towards the zenith, shows definitely that, in general, the brightness of the overhead sky gradually decreases from sunset to a minimum at about midnight, and increases after midnight.

To test whether the result was due to admixture with zodiacal light (it is questionable whether we should consider it as separate from night sky light), simultaneous photographs were taken on a few occasions of the spectrum of the sky with the spectrograph pointed approximately towards the pole star. These confirm that even in the north sky there is a distinct minimum of brightness within an hour of midnight. It may be mentioned that the nights were all perfectly clear. Occasional casual variations, such as have been noted by various observers in Europe and America, also occur.

If the excitation of the green line is directly or indirectly due to ultra-violet light from the sun, one would *a priori* expect a minimum brightness of the sky some time after midnight depending on the height of the effective layer of atomic oxygen. The maximum brightness observed in temperate latitudes at about this hour is in need of adequate explanation.

#### Anomalous Diamagnetism of Bismuth

BISMUTH when electrically or mechanically colloidalised shows a fall in its diamagnetic susceptibility value.<sup>1</sup> Doubts were raised by Prof Bhatnagar as to whether this fall in value could not be due to oxidation.<sup>2</sup> It was shown by me<sup>3</sup> that though a large part of this value was certainly due to oxidation, still there was a decrease in value which could be explained only by attributing it to reduced particle size, as in the case of graphite.

The problem has now been attacked in a different manner. Colloidal bismuth, mechanically prepared and purified by treatment with tartaric acid and alcohol, was investigated in the following way: A small quantity was sealed *in vacuo* in a small glass bulb. The deflexion was noted in a Curie balance

having for comparison a standard benzene bulb. The powder was then melted, and recrystallised by heating the bulb in an electric heater to about  $270^{\circ}\text{C}$  and very slowly cooling it. After noting the deflexion due to the bulb with the resolidified bismuth, that of the container alone was determined by breaking it open and dissolving out the metal with nitric acid. Experiments with similar bulbs and bismuth regulus showed no change of deflexion after heat treatment. But when bismuth powder was melted and recrystallised, the diamagnetic susceptibility rose nearly to the regulus value. Many samples of colloidal bismuth gave similar results.

These observations indicate that the fall in the susceptibility value with reduction of particle size in the case of bismuth is a genuine effect. Full details of this investigation will be published elsewhere.

### Photochemical Decomposition of Phosphine

It is rather surprising to find that, although the photochemistry of ammonia has attracted considerable attention since Warburg's<sup>1</sup> work, no corresponding experiments have been carried out with the equally simple molecule of phosphine. Such experiments have now been in progress in this laboratory for some time.

The absorption spectrum of phosphine consists of a region of continuous absorption beginning at about  $220\mu$  and continuing to  $185\mu$ , the limit of the spectrograph used. Preceding this continuous band there are three diffuse bands in the region  $220\text{--}230\mu$ . No fine structure is exhibited by these bands. The spectrum, like that of ammonia, would appear to be of the predissociation type.

Light from zinc or aluminium sparks readily decomposes the phosphine into hydrogen and phosphorus, which is deposited as the red variety on the walls of the insulation tube. The experiments on the direct photochemical decomposition have not yet been completed. The mercury photosensitised reaction has, however, been investigated in some detail. The rate of decomposition is about ten times that of ammonia under the same conditions. It is dependent on the diameter of the reaction tube, for, as the diameter is decreased—that is, the surface volume ratio increased—there is a decrease in the rate of decomposition. For example, in tubes of 2 cm, 1 cm, and 0.5 cm diameter, the rates are in the ratio 2.5 : 1.5 : 1. This would indicate that recombination of the products of dissociation occurs at the walls of the reaction tube. Argon has no effect on the velocity. On the other hand, oxygen increases the rate of decomposition as much as five times ( $p_{\text{PH}_3} = 0.05\text{ mm}$ ,  $p_{\text{O}_2} = 0.05\text{ mm}$ ), while the subsequent addition of argon (0.1 mm) still further increases this rate. These observations are most plausibly explained if it is assumed that oxygen attacks the products of dissociation, thus preventing their recombination. The resulting oxide molecules then initiate a stable chain reaction between the undecomposed phosphine and the oxygen.<sup>2</sup>

These results partly explain an interesting observation of Hinshelwood and Clusius,<sup>3</sup> who found that on illuminating a  $\text{PH}_3\text{--O}_2$  mixture below the lower critical explosion pressure, the pressure to which the mixture had to be compressed in order to obtain explosion was lower than that of the unilluminated gases. A mercury lamp with a chlorine-bromine

filter transmitting  $250\text{--}280\mu$  was used in these experiments. The effect was shown to have its origin in the phosphine molecule, but in view of the fact that phosphine itself does not absorb in the region  $250\text{--}280\mu$ , it would seem that the incidental presence of mercury vapour resulted in the phosphine being decomposed by excited mercury atoms into hydrogen atoms and probably  $\text{PH}$  or  $\text{PH}_2$  radicals, which produce the Hinshelwood-Clusius effect. Hinshelwood and Clusius concluded that the active material was present in the gas phase, but on repeating their experiment by exposing the mixture in one tube and determining the explosion pressure immediately after in another similar tube, the effect was not observed. That is, the effect is most probably a wall phenomenon, the illumination of the mixture producing a molecule or radical which is afterwards adsorbed on the walls, the latter are thereby enabled to reflect the chains more efficiently, thus decreasing the explosion pressure. It has also been found that pretreatment of the walls with atomic hydrogen results in a decreased explosion pressure.

### Structure of the Third Positive Group of CO Bands

THE third positive group of CO bands has been studied often before, but no satisfactory analysis of the bands seems to have resulted from it. Therefore we have photographed the bands in the second and third order of a 21-ft concave grating with 20,000 lines per inch. So far, we have studied the bands  $0\text{--}0$  to  $0\text{--}4$  with heads at 2833, 2977, 3134, 3305, and 3493 Å. The bands are due to a  $^3\Sigma\text{--}^3\Pi$  transition. The triplet separation of the  $^3\Sigma$  state is unnoticeable for  $J < 20$ . Under these conditions we must expect 15 branches if the resultant spin is not yet completely coupled to the rotational axis (transition from case *a* to case *b*). We found 13 of these branches and traces of the remaining two, which are too faint to be observed among the strong main branches. The five heads which are characteristic for the bands under low dispersion are the heads of the  $O_3$ ,  $O_2$ ,  $P_3$ ,  $P_2$ , and  $P_1$  branches (in the simplified notation of case *b*). The initial level shows very strong perturbations from about  $K = 16$  on, and slight irregularities also for very small  $K$  values. This fact makes an analysis of the higher lines of the bands much more difficult, and we have not yet completed this part entirely. The moment of inertia for the final state is  $16.5 \times 10^{-40}$ , and for the initial state approximately  $14.3 \times 10^{-40}$ . The character of the  $\lambda$ -doubling and the number of missing lines near the origin identifies the final electronic state as a regular  $^3\Pi$  state.

Our results are not in agreement with the analysis of Asundi,<sup>1</sup> who classified these bands as  $^5\Sigma\text{--}^5\Pi$  transitions. The fact, however, that the observed structure agrees perfectly with the theoretical expectation that practically all lines in the region investigated can be arranged into those branches, that all combinatorial relations are fulfilled within the limits of experimental errors, and that the perturbations of equivalent lines are identical in the sixty branches in which they occur seems to us a strong argument in favour of the correctness of our analysis.

Complete details will be found elsewhere.

## Research Items

**Pigmentation of Sussex School Children.**—Dr W R Dunstan contributes to the *Medical Officer* (March 19, 1932) a survey of 18,349 children attending the elementary schools of East Sussex, comprising both rural and urban communities. He has found, as did Prof H J Fleure in his survey of the population of Wales, that there is a decided tendency to the differentiation of local types. In this community, usually regarded as one of pure Saxon descent, red hair occurred in 4.9 per cent of the children examined, round Heathfield there was 8 per cent of red-haired children, while in Rye there was only 3 per cent. Flaxen hair had a general incidence of 7.7 per cent, along the northern area examined by Dr Dunstan it rose to 10 per cent, in Uckfield it fell to 4 per cent. Black hair occurred in 6.7 per cent of the 18,000 children surveyed, in the schools of Newhaven it had an incidence of 16.7 per cent, in Uckfield 12 per cent, in Rye only 2 per cent. In most points observed, urban children had the same degree of colouring as the children of the neighbouring rural district. There were exceptions, however. Rather unexpectedly, there was a decided preponderance of flaxen-haired boys in the town schools, and also of black-haired boys and girls, as compared with the corresponding rural children. The maps which Dr Dunstan has prepared to show the distribution of hair and eye colouring reveal distinctive areas and zones. If a population is stationary as regards residence, a differentiation into local types is to be expected. Whether the increased industrialisation of the home counties will lead to the break-up of these 'local pockets' remains to be seen. Dr Dunstan's survey has demonstrated that they still persist in East Sussex.

**The Drum in South America.**—In South America the drum plays a very small part, and, indeed, it has been doubted whether it existed on the Amazon and in the Guianas in pre-Columbian days and may not have been entirely of European introduction. In the southern area it takes the form of a hollow membrane-covered vessel, which, curiously enough, is filled with water when it is in use. This form also occurs in the extreme east of North America. In ancient Peru, judging from the Chimu pottery figures, the drum was more prominent, though no examples have as yet been recovered from the ancient graves. Nordenfalk holds the opinion that the true Indian drum had a membrane on one side only. A Chiriguano specimen, now in the Goteborg Museum, is made from a hollow log, one end of which is open, while a circle of wood, covered with skin, fits closely to the other. It is evidently of Peruvian derivation. Harcourt, on the other hand, holds that the Peruvian drums had parchment on both sides. All doubt is set at rest by three specimens, hitherto undescribed, which are illustrated in the *Journal de la Société des Américanistes*, N S, t 23, fasc 1, by Dr Karl G. Izikowitz, who examines the whole question in some detail. One drum, now in the Hamburg Museum, comes from Quillagua, Northern Chile. It is probably made of a hollow log of wood (diameter 26 cm). It cannot be examined, as it is entirely covered with skin. The second, in the Munich Museum, is also completely covered with skin, but owing to its condition the method of construction can be seen. It is made of slats of wood fastened by threads to two rods, one above the other, bent to form an oval (long axis 29 cm). These might from their size have been the originals of the Chimu drums. The third specimen, now in the Goteborg Museum, is from Southern Peru, probably Ica. It is a terra-cotta vase

with skin over the expanding mouth. It is analogous to the water drums of the Chaco, and probably, like them, was filled with water when played.

**Life History of *Paralepis*.**—No 10, vol 2 (Biology) of the Report on the Danish Oceanographical Expeditions 1908–1910 to the Mediterranean and adjacent seas, under the superintendence of Dr Johs Schmidt, contains two memoirs, A 13 "The *Sudidae* (*Paralepis*)", by Vilh Ege, and A 14 "Carangidae", by W Schnakenbeck. The pelagic fish genus *Paralepis* inhabits the North Atlantic and the Mediterranean. The specimens collected embrace upwards of 13,000 specimens, mostly post-larvæ at different stages, with a certain number of very young forms. The author has elucidated the life-histories of all the species investigated which, except for very few larval and post-larval stages, were previously unknown, and represent ten species, three of which are new. The characters used for distinguishing the species are the number of vertebrae and fin rays, length of head, dentition, position of the fins, and the length of the pectorals. These characters can be recognised in most of the older post-larvæ. To link them up with the younger larvæ, the position and number of the chromatophores, which are very characteristic of the species, are used. The first part is an introduction, the second is systematic, and excellent figures are given of a series of young of each species and also of the jaws, the third part deals with the biology of the post-larvæ, their horizontal and vertical distribution at different times and in different places, with relation to temperature and the probable time of spawning. The specimen from Polkerris in Cornwall, described by Day (1880–84) as *Paralepis coregonoides*, has been examined and pronounced to be *Paralepis coregonoides borealis* Reinhardt, which the author regards as distinct from *Paralepis coregonoides coregonoides*, with a more northerly distribution. He is also of the opinion that the post-larva from the Bay of Biscay, recorded by Holt and Byrne (1906), is probably this northern species.

**The Structure and Division of Chromosomes.**—With advances in genetic theory, the detailed structure of chromosomes and the manner of their division have become matters of increasing importance. In a critical study of mitosis in the root tips of diploid and tetraploid forms of *Narcissus*, Dr S Hedayatullah (*J Roy Micro Soc*, vol 51, p 347) has made observations which throw light on previous views and give a consistent picture of the chromosome as a structure which is double throughout the mitotic cycle, splitting in each metaphase into halves, which will separate in the following metaphase. The chromosome is thus double both in anaphase and prophase and in the interkinesis stage between. Cytologists have frequently regarded the chromonema and chromomere hypotheses as mutually exclusive, but here it is shown that by the fusion of the chromomeres in early prophase a continuous chromonema is formed, which then splits longitudinally in metaphase. The two threads in the matrix of the chromosome begin to twist around each other in anaphase, and so form in telophase appearances which have been mistakenly interpreted as due to a process of alveolisation. In telophase the chromonemata untwine and become chromomeric, and the resting nucleus is essentially composed of strings of chromomeres running parallel in pairs, not forming a network in the true sense. The cleavage

of the chromonema in metaphase is regarded as bringing about the longitudinal division of the gene thread in each mitosis. The fact that the chromosome is at all times essentially a double structure composed of two threads will need to be taken into account in future interpretations of the phenomena of meiosis.

**Ore Deposits of Nevada**—An important structural and economic study of the mining district of Goodsprings, Nevada, has been made by D. F. Hewett (*Prof. Paper*, 162, U.S. Geol. Sur., 1931). Stratified rocks range from Upper Cambrian to Recent. In early Tertiary times folding occurred, followed by thrusting and injection of sills and dykes of granite-porphphy. Normal faults accompanied by ore deposition are succeeded by still later faults which are older than a series of middle Tertiary volcanic rocks of the andesite-rhyolite suite. The ores include gold, deposited in granite-porphphy and adjacent carbonate rocks, oxidised copper minerals with accessory cobalt, nickel and silver, some of which occur near the granite-porphphy masses, and lead and zinc sulphides and oxidised ores mostly remote from outcropping bodies of intrusive rock. The copper deposits lie in Devonian or older beds, while those of lead and zinc are concentrated in dolomitised limestones of Lower Carboniferous age. Apart from the regional zoning of the ores and the distribution of alteration there is nothing to prove a genetic relation between the intrusive rocks and the lead and zinc deposits. Such indirect evidence, however, points here, as elsewhere, to a deeply buried mass of igneous material as the source from which the ore-solutions ascended.

**Earthquake Frequency in Northern Europe**—In *Sveriges Geologiska Undersökning, Årsbok* (1930), No. 1, K. E. Sahlström publishes a new seismological map of Scandinavia and Finland, showing by different intensities of blue colouring the total number of earthquakes recorded in that region during the period 1600–1925. It is an extension of a map lately published by H. Renquist (*Z. Geophysik*, vol. 4, p. 7) for Finland, and is made on the same novel plan. The regions in which seismicity in recent centuries has been strongest are along the west coast of Norway, between Stavanger and Molde and in another narrow belt farther north, the country around Oslo and eastwards towards Lake Venern, and the region round the Bothnian Gulf. An interesting brief discussion of the cause of the marked seismic activity of certain limited regions and the seismic quiet of others is given.

**Magnetic Anomalies in France**—In the *Annales de l'Institut de Physique du Globe de l'Université de Paris et du Bureau Central de Magnétisme Terrestre* (t. 9, Paris, 1931, pp. 210), eighteen papers on geophysics are included, together with the annual summaries of magnetic data from the two French magnetic observatories of Val Joyeux (for which hourly data are printed) and Nantes. Probably the paper of most novelty and interest is that on the anomalies of the earth's magnetic field over France, that is, the departures from the smooth distribution of isomagnetic lines most nearly fitting the observed field. This paper is illustrated by four charts showing, in colour, the anomalies in declination, inclination, horizontal force, and vertical force. In some of their main features these four charts show notable differences. The most striking anomaly is that in the 'Paris basin', extending in a narrow belt half-way across France, from the coast of the English Channel in a south-south-easterly direction. On the east of its centre line the declination is in excess,

and on the west in defect, by amounts surpassing half a degree in some places, the vertical force is in excess over the same region, and on both sides of the centre line, while the horizontal force shows no particular abnormality. The anomaly is not explicable in terms of the magnetic properties of the known geological strata in the region, and points to unknown influences deeper down.

**Monochromatic Atomic Waves**—Two ways for obtaining beams of atomic rays which have only a small range of velocities or de Broglie wave-lengths are described by I. Estermann, R. Frisch, and O. Stern in the *Zeitschrift für Physik* for Dec. 10. In one, a monochromatic beam of helium atoms is sorted out from a heterogeneous beam with a Maxwellian distribution by forming its wave-spectrum by diffraction at a crystal of lithium fluoride, and working only with diffracted beams coming off from the crystal within small angular ranges. In the other method, the Maxwellian beam is passed through a form of mechanical filter which consists of two parallel toothed wheels rotating on a common axis. This method, which has already been used by K. T. Compton and others, has given particularly good results with Prof. Stern's fine technique for this type of work, and has the great merit that the mechanical speed of the particles can be calculated from the speed of rotation and the geometry of the system. In this way, it has been found possible to verify rather closely that the distribution of velocities in the original beam conforms to Maxwell's theory, and to show that de Broglie's formula is correct to within two per cent for helium atoms, the diffraction being again performed at a lithium fluoride crystal.

**Some Properties of Cerium Ions**—We have received from Prof. D. M. Bose and S. Datta, University College of Science, Calcutta, a preliminary account of some new theoretical and experimental work bearing on the binding forces between atoms in crystals, exemplified particularly by the properties of the cerium ion  $Ce^{++}$ . Recent interest in this dates from the discovery made by de Haas and Becquerel, in 1929, that the magnetic rotation of the plane of polarisation by tysonite, which contains this ion, follows a modified Langevin formula which requires the effect to be due to a single electron bound in the ion in the simplest possible way, although Hund's theory shows that the state of the ion is decidedly more complex. Evidently some part of the elementary magnetic moment has become immobile in the crystal. The explanation offered for this is based on Stoner's theory of the magnetic properties of the ions of the first transition group of the periodic table, and is essentially that in this case the orbits of the electrons involved are held rigidly by the fields of near-by atoms, whilst the spin moments of the electrons are unaffected and can orientate in the applied magnetic field. Prof. Bose had already produced a closely similar immobilisation in ions of cobalt, nickel, and iron by changing these into complex forms, and it is now found that this also involves a shift of the absorption bands of their spectra towards the ultra-violet. This is attributed to the necessity for overcoming the orbital coupling forces within the complex when the electron jump associated with the absorption takes place, and it is shown that an extension of these ideas will account for the changes in the absorption spectra of both cerium and gadolinium ions which have been observed by Freed on cooling certain substances which contain them. Further evidence for the nature of the coupling forces which immobilise part of the ion is contained in a second letter received from Prof. Bose and Mr. Datta, in

which they outline a possible correlation between some new bands which they have observed in the ultra-violet absorption spectrum of the ion  $\text{Ce}^{+++}$  in solution and some of the lines in the ultra-violet emission spectrum of the same ion which were measured and classified by Badami last year. An explanation is offered, based upon the nature of the terms involved, of why the difference between their and Badami's wave-lengths is sometimes positive and sometimes negative.

**Sensitive Flames**—Whilst the behaviour of the sensitive flame is still imperfectly understood, a number of interesting experiments on the subject have been described by G. B. Brown (*Phil Mag*, Jan 1932). The best jet diameters lie between 0.5 mm and 5 mm, and the flame is always most sensitive to sound when it is on the point of 'flaring'. The position and construction of the tube supplying gas to the jet affects the sensitivity only in so far as it can alter the way in which the gas streams out of the orifice. The sound frequencies producing maximum or minimum disturbance are definite constants for any particular gas, no matter what kind of jet is used. The range of frequency to which gaseous streams are sensitive varies with the gas used and with the size and nature of the jet. With air the range is quite low (80-900), with unlit gas somewhat higher, and with ignited coal gas or hydrogen the range extends with different jets from 500 to more than 18,000 vib per sec. For a regular circular orifice the velocity for sensitiveness is high for a high-frequency range and low for a low-frequency range. It appears that sound does not, as has been generally assumed, precipitate the state of turbulence into which the gas stream is about to fall, but it causes regular undulations to proceed from the jet up the column,

the upper part of the column breaking into turbulence. The wave-length of these undulations depends, as would be expected, on the velocity of the column and the frequency of the sound. The most sensitive flames have marked directional properties.

**Discs and Conical Diaphragms in Sound Reproduction**—The use of conical diaphragms in the design of modern loud-speakers has stimulated interest in their behaviour from the physical point of view. In a recent paper by Dr N. W. McLachlan (*Proc Phys Soc*, Jan 1932), the results of experimental methods have been developed which lead to the determination of the effective mass of vibrating discs and conical diaphragms. It is shown that the 'effective' mass of a circular aluminium disc vibrating in air is variable. In the centre-stationary mode the effective mass attains a positive maximum before the zero value and a negative maximum after it. From the shape of the curves for a disc, it is possible to interpret those obtained for conical diaphragms. In the latter case the curves depend on the angle of the apex of the cone. When the apex angle is  $160^\circ$  the disc characteristics are still apparent. As the angle is reduced the properties peculiar to a conical diaphragm assert themselves. When the angle is nearly zero, the characteristics of a cylinder become apparent. The expression 'nodal circle' is sometimes used in connexion with conical diaphragms, but the actual lines of minimum amplitude traced by the lycopodium powder were quite irregular and occasionally discontinuous. The shape of the diaphragm during vibration is determined partly by (a) transmission loss, (b) acoustic load, and (c) reactive load due to accession to inertia. When impedance measurements are made in air and *in vacuo*, it is seen that (b) and (c) are absent in the second case.

### Astronomical Topics

**Application of Sound Films to Timing Solar Eclipses**—The Annual Report of Mount Wilson Observatory for the year 1930-31 refers to an ingenious method of obtaining the exact time and duration of totality in the very brief total eclipse of April 28, 1930. The Mount Wilson party was stationed at Honey Lake, California, which is at lat  $40^\circ 8' 20''$  N, long  $120^\circ 15' 30''$  W, altitude 4000 feet. Moving pictures with sound records were taken by the Fox Movietone News. The observers gave audible time signals about the time of totality, which were recorded in conjunction with the film showing the progress of the eclipse. The time of mid-totality was thus recorded as 19<sup>h</sup> 5<sup>m</sup> 51<sup>s</sup> U.T., which was 1<sup>s</sup> 7<sup>th</sup> earlier than the prediction, the duration of totality was recorded as 1<sup>m</sup> 2<sup>s</sup>, which was 0<sup>m</sup> 2<sup>s</sup> less than the prediction. It is worth noting that totality could frequently be timed in this manner, even if the weather is cloudy. At Colwyn Bay in 1927 the sky was densely overcast, but the passage of the moon's shadow on the clouds at the beginning and end of totality was plainly visible. As the seconds of Greenwich time were audible, distributed by wireless from Daventry, such a record would have enabled the times to be deduced at least to the nearest second.

**Another Search for Intra-Mercurial Planets**—Searches made in former eclipses have made the existence of intra-Mercurial planets very improbable. But the plates taken by Prof. Freundlich's expedition to north Sumatra in 1929 were so rich in stars that Herr von Klüber, of Potsdam Observatory, thought it worth while to make an exhaustive search for such bodies: the plates were compared with the control

ones taken six months later with the same instrument. The search established that there was no planetary body as bright as magnitude 9.5 in the regions of the plates that were more than  $40'$  from the sun's limb. The brightness of the corona obscured faint stars nearer the sun, but even in this region a body of magnitude 7 could have been detected. The search was worth making, and strengthens the conclusion that there is no body of appreciable size inside the orbit of Mercury.

**A Tenth Trojan Planet**—The object detected by Herr Reimmuth on Dec. 31 was at first thought to be a comet, but the suspicion of nebulousity round it was not confirmed, and a new orbit of it is given by Dr Kahrstedt in *Rech. Inst. Circ.* 547, based on observations on Dec. 31, Jan. 12, Feb. 6:

|                           |           |
|---------------------------|-----------|
| Epoch 1932 Jan. 17 0 U.T. |           |
| <i>M</i>                  | 305 0058° |
| $\omega$                  | 87 0034   |
| $\Omega$                  | 47 0466   |
| <i>i</i>                  | 32 9207   |
| $\phi$                    | 2 1893    |
| <i>n</i>                  | 294 549"  |
| log <i>a</i>              | 0.720566  |

There are now five known Trojans on each side of Jupiter, Achilles, Hector, Nestor, Agamemnon, Odysseus have longitude about  $60^\circ$  greater than Jupiter's, Patroclus, Priamus, Aeneas, Anchises, 1931 YA have longitude  $60^\circ$  less. If the names of Hector and Patroclus were interchanged, we should have Greeks on one side and Trojans on the other.

## Medical Research in Great Britain

FEW people can do more than glance through the majority of the scientific periodicals, reserving their attention solely for papers which deal with the subjects in which they are particularly interested. For those who wish to keep abreast of the times in medical science, perusal of the Report of the Medical Research Council\* is a convenient means of obtaining a review of recent work carried out in Great Britain. For those who desire fuller information on any subject, the lists of papers published by investigators working under the auspices of the Council will afford a starting-point.

As in previous years, the facilities of the Council have been increased by additions to its funds from various public bodies and private benefactors, by gifts of material from manufacturing firms, and by the fact that more than half of the work sponsored by the Council is carried out by investigators in university laboratories, where the general facilities of the laboratory are at their disposal. Particular investigations have been aided by the Empire Marketing Board, the Dental Board of the United Kingdom, the British Empire Cancer Campaign, the Distemper Research Council of the *Field*, and the Foot-and-Mouth Disease Research Committee. The material supplied by different firms has permitted extensive investigation into the control of dental decay, puerperal fever, and other infections by dietetic means, as well as facilitating the search for pure vitamin D, to mention only two examples.

The two senior members of the Council, Prof. T. R. Elliott and Prof. J. B. Leathes, retired at the close of the year under review, their places being taken by Lord Dawson of Penn and Prof. E. Mellanby. It is also noted in the Report that a Committee of the Privy Council for Agricultural Research and an Agricultural Research Council have now been appointed. With their formation the full triad of research organisations under the Privy Council is now completed. They deal together with the three main departments of man's activities with material things: the Agricultural Research Council with the production and protection of plant and animal life needed for human use, the Department of Scientific and Industrial Research with the materials and methods used in all forms of manufacturing industry, and the Medical Research Council with the proper development and use of the human body in all conditions, as well as with its protection from disease and accident and its repair.

The Medical Research Council awarded eight travelling Rockefeller medical fellowships and two Dorothy Temple Cross research fellowships in tuberculosis for the academic year 1931-32. During the past year the publication of a "System of Bacteriology" in nine volumes was completed and financial aid has been brought to *Nutrition Abstracts and Reviews*, in which the Imperial Agricultural Bureaux Council and the Reid Library of the Rowett Institute, Aberdeen, are also interested.

This year's Report reprints in an appendix the Council's memorandum on patent law in relation to medical research, which was submitted for consideration by the Departmental Committee on the Patents and Designs Acts and Practice of the Patent Office, 1929-31, since the Council does not believe that the questions at issue in the case of medical patents can long await renewed attempt towards their solution. The objections to the operation of the Patent Law in the field of biology and medicine are three in number:

First, the discovery of new facts in the medical field may lead, obviously and at once, without any intervening steps of ingenious invention, to valuable practical uses; discovery and invention cannot be clearly distinguished as in the inorganic field. Secondly, biological discoveries in their first phases are necessarily in the form of vague knowledge, and patents are likely to be drawn in wide terms that really go beyond the knowledge of the moment, for example, the Steenbock patent, controlling the commercial production of vitamin D by a natural process, covered the production of a substance of undetermined composition from an unknown constituent of certain complex materials by an action not then understood. It is now claimed to cover the production of calciferol or pure vitamin D from pure ergosterol, knowledge which is of more recent date and of independent origin. In the third place, medical discoverers in Great Britain rarely take out patents, so that the law works capriciously in favour of the few who break the tradition, or of the foreigner. The Council recommends that medical discoveries should not be patentable.

The National Institute for Medical Research carried out much work in connexion with biological standards, especially in preparation for the meeting of the Permanent Commission on Biological Standards (Health Organisation of the League of Nations) held in London at the end of June, which dealt with sera and bacterial products and the vitamins. Standards for gas gangrene antitoxin, diphtheria toxin for the Schick test, and for vitamins A, B<sub>1</sub>, C, and D were adopted at this conference. Gas gangrene antitoxin has now been scheduled under the Therapeutic Substances Act. The National Institute is also preparing the standards for vitamins A and D, carotene and an oily solution of irradiated ergosterol respectively, and is acting as the distributing centre for these as well as for the standard for vitamin B<sub>1</sub>, a dried adsorption product, on fuller's earth, of the active constituent of rice polishings, supplied by Prof. Jansen. The Institute already holds the international standards for insulin, digitalis, strophanthidin, and certain organic arsenical preparations. In addition, it prepares and maintains for Great Britain all the standard preparations required for substances scheduled under the Therapeutic Substances Act.

During the year the Council formed the Therapeutic Trials Committee, under the supervision and authority of which clinical trials of new substances may be organised. Conditions have been made with the Association of British Chemical Manufacturers under which new substances will be accepted for clinical study. It is also expected that other committees of the Council, such as the Chemotherapy and Sex Hormones Committees, will bring forward new synthetic compounds or biological products for early clinical appraisal under controlled conditions.

Brief reference must be made to some of the researches carried out by members of the staff of the National Institute and by other investigators on the Council's staff or provided with grants-in-aid. W. J. Elford has prepared a series of graded collodion membranes of which the pores have a uniform and measurable size and yet are sufficiently strong for bacteriological work. By means of these filters it has been possible to determine the size of the particles of a number of different viruses. Thus the diameter of the vaccinia virus ranges from 0.125  $\mu$  to 0.175  $\mu$ , that of infectious ectromelia of mice from 0.1  $\mu$  to 0.15  $\mu$ , that of a bacteriophage from 0.02  $\mu$  to 0.08  $\mu$ , whilst that of foot-and-mouth disease is of the minute size of 0.008-0.012  $\mu$ . The size of the virus particles of

\* Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the year 1930-1931. (Cmd. 4008) Pp. 153 (London: H.M. Stationery Office, 1932.) 2s. 6d. net.

infectious ectromelia agrees with that found by J E Barnard by the methods of ultra-microscopy

The vaccine-virus method for the immunisation of dogs against distemper is now firmly established and its value has been amply demonstrated. It will be possible to bring the research work to an end in the near future. The difficulties in the commercial production of this preparation have now been overcome. Inquiry of masters of foxhounds has shown that the incidence of infection among immunised animals is only 1.4 per cent and the mortality 0.3 per cent, whereas without inoculation the incidence among young foxhounds is nearly a hundred per cent and the mortality is frequently 50 per cent and may be 75 per cent. G W Dunkin and P P Laidlaw have also succeeded in preparing a hyper-immune serum which can be used in the incubation period of the disease or in its treatment, as well as in the production of immunity by injection simultaneously with the virus.

W E Gye and W J Purdy have continued their work on the viruses of avian tumours and have published their results in "The Cause of Cancer" (1931). In the sera obtained after injecting tumour filtrates containing the active agents into other animals, two kinds of antibodies were detected, one directed against a factor in the infective agent which is specific to the cells of the host, and the others adapted to an extrinsic factor of this agent. The viruses from most of the fowl tumours are serologically identical, but

Fujinami's fowl tumour, which is also transmissible to the duck, yields a virus which is immunologically distinct from the others.

M Greenwood, W W C Topley, and J Wilson have continued their studies in experimental epidemiology. From a study of the virus disease, infectious ectromelia, in mice, it is concluded that herd immunisation in bacterial and virus infections may be fundamentally different. In mouse typhoid, an immunised group will withstand a period of acute exposure to risk better than untreated animals, but, provided the exposure is continued, the general effect on the herd will be relatively trivial. In the case of a virus disease, it is probable that if admission to an infected herd were restricted to immunised animals, the herd mortality might be completely arrested. Experience with human diseases, in which the immunity produced is antitoxic rather than antibacterial, suggests that such infections behave as virus rather than bacterial infections.

In conclusion, it may be mentioned that reference is made in the Report to the work of Bourdillon and his colleagues on the preparation of pure vitamin D, as well as to the work carried out on the relation between diet and dental disease, and diet and infantile anaemia, summaries of many of these researches have already appeared in our columns. Work has also been continued, under the direction of E Mellanby, on the relation of diet to certain types of nervous disease, as well as to goitre and puerperal infection.

### Science and Economic Values

IN a paper before the London Section of the Society of Chemical Industry on Feb 1, Mr H A F Lindsay, India Trade Commissioner, dealing with "Modern Trade Tendencies and where they are leading", referred to the pronounced tendency to shorten stocks and to place the main responsibility on the primary producer. The shorter stocks carried in the chain between producer and consumer and the closer contact between producer and consumer are responsible in large measure for the violent fluctuations of price which are so prominent a feature of the markets to-day. A return to the practice of stock-holding by intermediaries is not probable, and accordingly the contribution which science renders in speeding up and rendering more accurate and general the trade information available for the world's markets is an important factor in stability, if only as assisting the spread of the practice of long-term contracts.

Trade cannot be established on a really satisfactory basis until the prices of raw materials and manufactured goods are brought close together, and towards this scientific methods are assisting by gradually increasing the output of the primary producer—whether in quantity or quality or both—and thus increasing the profits of agriculture, by bringing down the price and improving the quality of manufactures, and by slowly reducing the costs of distribution and transport. A new order of retail selling in which retail prices are fixed by the manufacturer, allowing a sufficient margin for retail and other distribution costs, has the merit of being scientific, but low whole-

sale prices cannot induce increased demand unless the public secures the benefit of a fall in the wholesale prices of any given commodity.

Mr Lindsay further suggested that our economic relations, whether national or international, are losing much of their instinctive value and acquiring new and more conscious values. New principles which are checking the operation of the old 'laws' of supply and demand may prove to be better suited for the changed conditions of modern life, and the extent to which humanitarian factors now affect the level of wages may only be an example of the passing of instinctive into conscious control, in which the humanitarian and the economic aspects are finally reconciled.

So far as scientific discoveries tend to cheapen production and eliminate waste, by stimulating demand they simultaneously tend to encourage the factors the strength of which increases with every swing of the pendulum away from equilibrium. So far as synthetic products are concerned, science appears to be co-operating most closely with economics, and it is only in its quicker response to the transition from an ideal of competition to an ideal of co-operation that science can be said to have outstripped economics. The new ideal of efficiency attained by mankind working consciously, constructively, and in co-operation towards a common goal does not eliminate competition but subordinates it to constructive forces, among which science is pre-eminent, and which are more qualified to exert deliberate and conscious control.

### Mechanism of the Combustion of Methane

THIRTY years have elapsed since Profs W A Bone and R V Wheeler first studied the combustion of methane and were led to the view that oxidation takes place through successive stages of hydroxylation of the hydrocarbon. In view of suggestions made in recent years that the initial products

of combustion might be peroxides rather than hydroxides, the investigation has been resumed and some important results are embodied in two recent papers.<sup>1</sup> In the first of these, Prof Bone and Mr R E Allum describe the course of the reaction at atmospheric pressure, while in the second, Dr D M Newitt

and Mr A E Haffner discuss the effect of pressures, varying from 48 to 150 atmospheres, upon the same reaction

The low-pressure experiments were carried out in silica vessels, which could be heated in an electric furnace to about 450° C and suddenly chilled by immersion in ice water, so that the process could be arrested and the products analysed, while the high-pressure experiments were conducted in chambers of special steel, which could be made to communicate with an expansion chamber at any moment. Precautions were taken to dissipate the heat of reactions sufficiently to counteract any rise of temperature, by diluting the original gas mixtures with excess either of the hydrocarbon or of indifferent gases. Varying proportions of the reacting gases were used, and the effect of adding water vapour and other gases to the carefully purified and well-dried mixtures was also studied. The results are in complete agreement with the original view that oxidation proceeds by the process of hydroxylation.

In the first place, in these experiments, as in former investigations, it has been shown that the most reactive of all the mixtures is that expressed by the formula  $2\text{CH}_4 + \text{O}_2$ , which corresponds with the formation of methanol. Secondly, although there is a considerable deficiency of oxygen in this mixture for complete combustion of the hydrocarbon, neither free carbon nor free hydrogen was ever liberated, nor was any trace of a peroxide detected at any stage of the reaction. The most conclusive evidence, however, lies in the actual isolation and identification of the primary product, methanol, which under high pressure is formed in considerable amount. It was to be expected from stoichiometric relationships that increased pressure would favour the formation of the alcohol at the expense of the aldehyde, and the authors are to be congratulated on being able to show that this expectation has at last been realised.

It appears from these results that the effect of increasing the pressure is to increase not only the amounts of methanol and formaldehyde which survive, but also the ratio of alcohol to aldehyde. Moreover, for each pressure there is a definite temperature (not the lowest effective temperature) at which the yield of alcohol reaches a maximum. The alcohol was characterised by means of its *p*-nitrobenzoyl derivative, and the complete absence of peroxides was inferred from the failure of the titanous sulphate reaction, which is sensitive to two parts per million.

The oxidation is mainly a surface effect, characterised by a marked period of induction, which may be obliterated by the addition of certain vapours. The authors do not discuss the cause of this period of induction, but they state that the end of it synchronises with a certain small accumulation of formaldehyde, which persists throughout the reaction period.

### University and Educational Intelligence

APPLICATIONS are invited for grants from the Thomas Smythe Hughes Medical Research Fund of the University of London. They should reach the Academic Registrar, University of London, South Kensington, S W 7, not later than May 16.

THE latest date for the receipt of applications for grants from the Dixon Fund for the assistance of scientific investigations is May 14. The applications, accompanied by the names and addresses of two references, should be sent to the Academic Registrar, University of London, South Kensington, S W 7.

No. 3258, VOL. 129]

OPTOMETRY, defined in the New York State law as "the employment of any means other than the use of drugs, for the measurement of the powers of vision and the adaptation of lenses for the aid thereof", offers opportunities of a career for which a four years university course is held to be a suitable preparation. A bulletin received from Columbia University, New York, describes in detail a curriculum analogous to other professional courses designed to occupy a student's entire time during four years, of which the first two include such fundamental subjects as English, German, contemporary civilisation, mathematics, physics, chemistry, physiology, etc., and the last two are devoted almost exclusively to professional studies bearing directly on the theory and practice of optometry. That these courses are held by qualified judges to be in fact a suitable preparation for practical work seems to be proved by the fact that during the past ten or twelve years optical societies, instrument makers, and others specially interested in the development of optical engineering or in training optometrists have contributed gifts of apparatus valued at 25-30 thousand dollars.

### Calendar of Geographical Exploration

April 10, 1627 — South Coast of Australia

The *Gulden Zeepard*, commanded by Francis Thyszoon, with Pieter Nuyts on board, arrived in Batavia, Java, after having in a single voyage discovered the whole south coast of Australia so far east as long 133°. The Pieter Nuyts Archipelago indicates the eastern limit which they reached, and the land north of the Great Australian Bight was long known as Pieter Nuyts Land.

April 15, 1928 — An Arctic Flight

Starting from Point Barrow, Alaska, Capt G H Wilkins and Lieut Eielson flew across the Arctic Ocean, reaching Spitsbergen in 20½ hours and covering 2200 miles. Wilkins was knighted on his return.

April 16, 1245 — A Papal Envoy to the Grand Khan

John de Plano Carpini, a Franciscan, set out on a mission from the Pope to the Grand Khan of the Mongols. He travelled via Ciacow and Kiev, went down the Dnieper, crossed the Don near its mouth, and reached the Volga about a hundred miles north of the modern Astrakhan. He then went across the Aral-Caspian depression to the Syr Daria, went past Lake Ala Kul, and arrived at the camp of the Mongols near Karakoram on July 22, 1246. He left a very accurate and detailed description of his journey, giving accounts of the climate and vegetation of the steppe and of the customs of the nomads. He described the drainage of South Russia, giving the Slavonic names of the rivers.

April 16, 1906 — Mountain Ascents by the Duke of the Abruzzi

Luigi Amadeo, Duke of the Abruzzi, left Naples for Mombasa on an expedition to Mt Ruwenzori. He was the first to reach its twin summits, which he named Margherita and Alexandra. His party made a detailed survey of the Ruwenzori Range. In 1897 he had been the first to ascend Mt St Elias in Alaska, and in 1899 he organised a polar expedition, which reached lat 86° 3' N, at that time a record. In 1909 he explored the Central Karakoram in the Himalayas, and achieved a record for height by climbing peak K2.

## Societies and Academies

## LONDON

Physical Society, Feb 5—R M Davies The rapid determination of the moisture-content of seeds Two new methods are described, the first involving the use of a thermionic oscillator, the second a direct-current galvanometer and a battery The first method is best suited for use with large-grained seed, whilst the second can be used with all types of seed—M C Johnson Surface heating by neutralised positive rays before and after return to normal state This is shown by investigating the disturbance of a bridge balance between two filaments accurately aligned across the beam at different distances along its path Excess heating occurs in that filament which receives the larger proportion of atoms in excited states The variation of this excess heating with the potential driving the discharge is quantitatively in agreement with the variation of concentration of excited atoms at the different distances along the beam this latter is calculated from Wien's experiments on the exponential decay of excited states along the path of neutralised positive rays—E V Appleton and F W Chapman The collisional friction experienced by vibrating electrons in ionised air The variation of the radio-frequency conductivity of ionised air with pressure has been studied experimentally at frequencies of the order of  $10^9$  From the measurements of the critical pressure at which such conductivity is a maximum, the magnitude of the collisional frictional forces experienced by vibrating electrons has been estimated

Geological Society, Feb 10—S James Shand The reaction between granitic magma and limestone at Palabora, Transvaal (lecture) The Palabora granite is intrusive among ancient schists which include bodies of crystalline limestone The hill Lulu Kop is a mass of metamorphosed dolomitic limestone isolated in the granite Between granite and limestone there is a belt of flat ground, within which all the rocks exposed are rich in diopside and apatite, they vary from shonkinite to pyroxenite and massive apatite Between these rocks and the granite there is a narrow belt of diopside-arfvedsonite-syenite The evidence indicates extensive reaction between granitic magma and limestone, producing syenite and shonkinite, and it is suggested that the pyroxenite was formed by the sinking of diopside crystals from the contaminated magma—S James Shand The lavas of Mauritius The lavas of Mauritius are mainly basalts, some rich in olivine and others almost or quite free from it No feldspaths have been detected, but some of the rocks are of the 'pacificite' type, having nepheline in the norm Soda-trachyte was found at two localities, and must be regarded as a differentiate of the basaltic magma

## DUBLIN

Royal Dublin Society, Feb 23—W S E Hickson and K C Bailey The inhibition of chemical reactions (5) The inhibition of the absorption of ethylene by sulphuric acid The surface tension of solutions of pyridine in sulphuric acid The absorption of ethylene by sulphuric acid is inhibited by pyridine and other substances The amount of inhibitor required is relatively large The inhibitors investigated raise the surface tension of sulphuric acid and are therefore present in low concentration at the liquid-gas interface, at or near which the main reaction takes place—James B Butler and Anne Humphries On the growth in artificial media of *Catenaria anguillula*, a chytridiacean fungus, parasitic on the ova of *Fasciola hepatica* Various com-

binations of agar, extract of fluke ova, and egg albumen gave positive results The fungus grew out from the infected ova, and formed an extensive thallus, containing in one instance upwards of sixty zoosporangia Germination of the zoospores in the artificial media was observed The zoospores developed profuse growths of hyphae, which advanced to the formation of zoosporangia The zoosporangia in their turn produced zoospores and dehiscence tubes—James B Butler—On a method of determining the depth of penetration of wood-boring beetles in structural timber A modified form of laryngoscope was shown which could conveniently be used for exploring the surface of a half-inch hole bored in the beam to be tested

## EDINBURGH

Royal Society of Edinburgh, Feb 1—Frederick Walker Differentiation in the sills of Northern Trotternish, Skye The sills intrusive into the Jurassic strata of Northern Trotternish represent the continuation north of the great group of basic sills described by Dr Harker They were, however, injected under a much thicker cover than the more southerly examples, and therefore show the effects of differentiation to a far greater extent Picrite-dolerite sills are very common, and teschenites are also to be found Gravitational settling of olivine *in situ* may be demonstrated in more than one sill, but the mode of differentiation in other cases is less certain—Gec. A Cumming A study of the San Andreas rift and adjacent features near Redlands, California The fault zone is composed of numerous interlacing faults tending roughly to parallel the master fault The fault planes are in general nearly vertical Horizontal shearing appears to be the dominant movement, but in this area there is also evidence of great vertical movements A major branch fault, the Mission Creek fault, is characterised by the presence of a narrow ribbon of steeply dipping Tertiary sediments, traceable for miles, faulted between immensely older gneisses—G W Tyrrell Contributions to the stratigraphy of the Stor Fjord region of Spitsbergen Numerous sections in the gently inclined Mesozoic rocks were described Fossil determinations show that the western coast of the Stor Fjord is composed mainly of Jurassic and Cretaceous rocks, while Barents and Edge Islands on the east are built of Triassic strata—G W Tyrrell and E S Sandford Tectonics and petrology of the dolerites of Spitsbergen A great dolerite sill-swarm of Lower Cretaceous age is distributed over 50,000 square miles of the Spitsbergen archipelago The petrography of the rocks, with two new analyses, is described, and their relations to the structural lines and tectonic history of Spitsbergen are elucidated.

## PARIS

Academy of Sciences, Feb 22—A Lacroix The intrusive and vein-containing rocks of the granitic and sedimentary region of the north of Tibesti—J Constantin Climatic degenerescence of the potato.—Armand de Gramont The factors of reflection and transmission of some metals deposited by cathode sputtering The results differ with the gas present deposits formed in argon are generally the best. Good mirrors can be deposited with tin, and this metal has the advantage that the films are less alterable in air than those of silver—Henri Lagatu, Louis Maume, and Mlle Lucienne Cros Study of the variations in the amounts of nitrogen in very localised points of the leaf of the vine—Theobald Smith was elected *Correspondant* for the Section of Rural Economy, and Jules Schokalsky *Correspondant* for the Section of Geography and Navigation—Miron

Nicolesco The problem of Riquier—S Samielevici Singular integral equations—Mariani Relativity and quanta—Edouard Callandreau A property of circular cylinders submitted to torsion—Ch Féry and N Stoyko The isochronism of a pendulum maintained by an impulse acting after the vertical—Al Proca A new characteristic of Dirac's electron—Louis de Broglie Remarks on the first integrals of wave mechanics—L Bouchet The influence of radioactive bodies on the Volta effect—R Forrer The law of discontinuous distribution of the Curie points—B Demetrovic The pseudo-reflection of the X-rays—Ion I Agarbiceanu The absorption spectrum of iodine—E Darmon and Yeu-Ki-Heng The influence of thorium salts on the rotatory power of tartaric acid and the tartrates Thorium forms complex compounds with tartrates The large rotations observed are due to the formation of true chemical compounds—J Cabannes and A Rousset Molecular symmetry and diffusion spectra—Mme Irène Curie and F Joliot The effect of absorption of  $\gamma$ -rays of very high frequency by projection of light nuclei—Morice Letort Five new oxidation-reduction indicators—E Cornec and H Krombach The equilibria between water, potassium chloride, and sodium chloride from  $-23^{\circ}\text{C}$  to  $+190^{\circ}\text{C}$ —Mlle O Hun Boiling point study of the molecular equilibria of pyrocatechol in solutions of calcium chloride and barium chloride—E Vellinger The rotatory power of some aminoacids as a function of the acidity (pH)—Lucien Andrieux The preparation of the mixed borides of thorium and cerium—L Bert and E Andor A new method of preparation of the  $\beta$ -chlorallyl bromide and iodide—Er Toporescu Studies on the inversion of sugar—Mme Ramart-Lucas The parallelism between colour and reactivity of a chromophore group—P Fleury and J Courtois The general character of the precipitation of sugars and the polyols by the hydroxides of the heavy metals in alkaline media—Mlle M Th François The acidity of castor oil The free fatty acids contained in castor oil are strongly retained by the neutral glycerides, and separation by physical methods appears to be impossible—Paul Gaubert Spherulites of helenine—J P Arend The genesis of ooliths—Raymond Furon New observations on the Cretaceous rocks of the Gabon coast—Mlle Lucienne George Observations on *Sorbus confusa* (= *S. aria* + *torminalis*)—J Trochain The biology of two Commelinaceae, *Commelina Forskaleri* and *C. benghalensis*—E Bachrach and G Morin A new (conditional) acquired reflex—Pierre Girard and Mme L Guastalla The electrophoresis of biological media—F Vlès and A de Coulon An intervention of electrostatic conditions in the appearance of certain spontaneous cancers

Feb 29—The president announced the death on Feb 28 of M G Bigourdan, of the Section of Astronomy, president of the Academy in 1924—A Lacroix The composition of the orthose lavas of the Tibesti volcanoes—Paul Pascal and Mme Rechid The hexametaphosphates A description of the preparation and properties of a new sodium hexametaphosphate,  $\text{Na}_6(\text{PO}_3)_6 \cdot 10\text{H}_2\text{O}$  This salt is regarded as a definite individual, and resembles the monometaphosphate in that it can be heated to any temperature without undergoing modification—Pierre de Vanssay was elected *Correspondant* for the Section of Geography and Navigation—Claude Chevalley The structure of the theory of the body of classes—D Belorizky The nature of the impacts in the problem of three bodies with three degrees of freedom—Thadée Banachiewicz The determination of the orbit from two heliocentric

points—L Goldstein The multiple excitation of complex atoms by impacts with electrons—A Guillet An electro-dynamical arrangement for the measurement of small mutual inductances Application to the examination of micrometers—R Forrer Verifications of the law of discontinuous distribution of the Curie points—R Ricard The first spark spectrum of mercury—Paul Soleillet The mean duration of life of the cadmium atom in the excited states  $^3P_1$  and  $^1P_1$ —E Cornec and H Krombach A physical method for the determination of potassium chloride in sylvinites The method is based on the fall of temperature resulting from the addition of potassium chloride to a saturated solution of sodium chloride Comparisons between results obtained by this method and the usual perchlorate method are given—Louis Chassevent Anhydrite and its formation An explanation of the apparent contradiction between the results of van't Hoff and those of Jolibois and Lefebvre—V Auger and Mme Poulenc-Ferrand Cupric carbonate Normal copper carbonate ( $\text{CuCO}_3$ ) has not yet been prepared, and it appears improbable that it can be prepared by a wet method—J Marçais The Cretaceous and the Nummulitic in the eastern Rif—Antonin Lanquine The accidents of the western edge of the Jurassic *Barres* between Belgentier and Néoules (Var)—P Fallot The extension towards the south-east of the marginal overlapping of the limestone chain of the Spanish Rif—Mlle M Goldsmith The proportion of the sexes in *Galleria melonella* While under normal conditions of temperature and diet the two sexes occur in practically equal numbers, if the food is insufficient, males predominate (17 per cent females)—P Durand and J Laigret Pustular fever (fièvre boutonneuse) and 'Marseilles fever' Crossed immunity A first attack of fièvre boutonneuse of Tunisian origin confers complete immunity against another Tunisian virus Similarly, a first attack due to a virus of Marseilles origin confers immunity against a Tunisian virus

#### ROME

Royal National Academy of the Lincei, Nov 1—S Pincherle A special linear operator (3)—Luisa Pelosi Maximum and minimum chords normal to a hypersurface By somewhat complicated calculation Bonnet determined (in 1843) the normal to a given ellipse (or parabola) for which the chord within the curve is a minimum, and found that such chord is tangential to the evolute of the ellipse at the point where it meets the ellipse It is now shown that this result is capable of generalisation, and that if a chord normal to a hypersurface is such that the segment of it contained in the hypersurface is a maximum or a minimum (without being binormal to the surface), this segment is equal to one of the principal radii of curvature of the hypersurface—B Hostinsky Integration of linear functional transformations (2)—A Quarleri Theory of the 'wake' in perfect liquids case of the round cylinder—G Lampariello Waves of discontinuity in the more general elastic media The existence in the most general elastic medium of three possible waves is established, the direction of propagation of each of them being determinable by constructing the corresponding bicharacteristics—A Corbellini and L Barbaro Abnormal decomposition of the tetrazo-derivative of 2,2'-diamino-1,1'-dinaphthyl The acidic compound formed as a result of this decomposition is, most probably, [4,5-(naphtho-1',2')-pyrazolyl (3)]-orthocinnamic acid—G Mezzadrol and E Vareton Contribution to the study of the photosynthesis of glucides in ultra-violet light from aqueous solutions of activated carbon dioxide The formation of formaldehyde, glycollic aldehyde,

and reducing sugars on exposure of carbon dioxide solution to the action of ultra-violet rays is greatly enhanced by the presence in the solution of colloidal calcium or magnesium carbonate—G Zanoni. Certain correlation phenomena in plants. Experiments with *Solanum pseudocapsicum* and *Jasminum lucidum* show that the action of light on leaves exposed to it modifies the transparent green colour according to a kind of cyclic curve during the twenty-four hours of the day. With this local action, there corresponds a diffusion of the reaction, by which the leaves of the branches kept in the dark exhibit, more or less rapidly, the colour changes of the leaves subject to direct illumination—L Buccianto. Survival of embryonic tissues of the hen kept in Ringer's solution at low temperatures. The permanence of embryonic tissues of the hen in Ringer's solution at 5°-10° C permits of the protracted survival of the elements of the tissues, but varies markedly in degree for different tissues. This phenomenon is probably accompanied by progressive subtraction of trophic substances, which diffuse from the cells into the liquid. Indeed, the addition of embryo juice is an almost indispensable condition for the cultivation of tissues in Ringer's solution, in a culture medium of plasma alone, the tissues either fail to grow or grow only to a very slight extent—Aldo Spirito. Experiments on grafting with the edible frog (3)—O Marcucci. Grafting experiments with amphibia—Giulio Cotronei and Celso Guareschi. Zoological constitution and grafting (8). Experiments with Anura and Urodeles—A Galamini. Course of fasting and re-nutrition in ovariectomised albino rats (1). The phenomena observed with these rats during fasting and during subsequent feeding are substantially the same as with the normal rats—A Galamini and E Serianni. Modifications of glucosuria and hydremia resulting from the administration of glucose and water—Giuseppe Levi. Obituary notice of Albert Brachet.

## VIENNA

Academy of Sciences, Dec 3—N Froschl, A Maier, and A Heuberger. The catalytic reduction of chlorides of dibasic acids—N Froschl and J Harlass. The preparation of naphthalene-dicarboxylic acid—N Froschl and A Heuberger. The acetalisation of polyvalent alcohols with mono- and di-ketones—N Froschl and J Harlass. Attempts at the synthetic preparation of agaricic acid—J. Zellner. The chemistry of lichens (1) *Peltigera canina*—J. Zellner. The chemistry of halophytes (3) *Sueda salsa*—C G Danoff and J Zellner. Contributions to comparative plant chemistry. Chemistry of barks. Various substances in the barks of mountain ash and edible chestnut—F Feigl and P Krumholz. The action of alkali alcoholates on iron pentacarbonyl. Salts of iron, barium and mercury can be obtained corresponding to a hydrogen iron carbonyl—L Schmid and L Haschek. Cryoscopic determination of the molecular weights of sugars and of mulin in liquid ammonia—K Grafi. Photometric observations of the Milky Way and of the zodiacal light in Majorca—T Pintner. The little-known and unknown as regards tapeworms—E Tschermak. Artificial illumination as a stimulus in hot-houses. For plant-breeders and scientific genetics it is becoming worth while to use cheap electric current in conjunction with gaseous carbon dioxide, especially in the winter months. In this way two generations can be raised indoors and a third in the open during one year, also artificial cross-fertilisations succeed indoors in winter—Y. Lebzelter. The anthropology of the No-gau bushmen on the lower Omuramba Epukiro in South-West Africa. Measurements are given. The No-gau are allied to the Kung.

No 3258, Vol 129]

## Forthcoming Events

## FRIDAY, APRIL 8

- ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30—Sir Richard Burn. Recent Developments in Land Revenue and Rent Policy in the United Provinces.  
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Royal Victoria Hotel, Sheffield), at 6—T G Elliot and Dr W Cullen. Special Alloy Steels as applied to Chemical Engineering.  
INSTITUTE OF FUEL (East Midlands Section) (Annual General Meeting) (at University College, Nottingham), at 7—V B Harley-Mason. Conditioning of Boiler Feed Water.  
SOCIETY OF DYERS AND COLOURISTS (Scottish Section) (Annual General Meeting) (at George Hotel, Glasgow), at 7 15—J Muir. Some Notes on pH Control by Colorimetric Methods (with demonstrations).  
OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at College of Technology, Manchester)—Annual Meeting.

## APRIL 8 TO 11

- CONGRESS OF GERMAN PHARMACOLOGICAL SOCIETY (at Wiesbaden).

## MONDAY, APRIL 11

- ROYAL SOCIETY OF MEDICINE (United Services Section) (Annual General Meeting), at 4 30—Surg-Commr W H Edgar. Scarlet Fever: an Effort in Preventive Medicine.

## APRIL 11 TO 14

- CONGRESS OF GERMAN SOCIETY FOR INTERNAL MEDICINE (at Wiesbaden).

## TUESDAY, APRIL 12

- INSTITUTE OF ELECTRICAL ENGINEERS (Scottish Centre) (Annual General Meeting) (at 39 Elmbank Crescent, Glasgow), at 7 30—W B Hird and J B Mavor. Electrically Driven Underground Conveyors in Coal Mines, and their Economic Advantages.  
INSTITUTE OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7 30—Annual General Meeting.

## WEDNESDAY, APRIL 13

- INSTITUTE OF FUEL (London Section) (Annual General Meeting) (at Chemical Society), at 6—Dr E S Grumell. Evaluation of Coal from the Users' Standpoint.  
ROYAL SOCIETY OF ARTS, at 8—J R I Brooke. Rural Industries: their Organisation and Development (Lecture).

## THURSDAY, APRIL 14

- INSTITUTE OF METALS (London Local Section) (Annual General Meeting) (at 83 Pall Mall), at 7 30—Discussion on Welding, Brazing, and Soldering.

## FRIDAY, APRIL 15

- SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Zoology, University Museums, Oxford), at 10 30 A M, 2 30, and 5 30.  
ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee), at 2—J H Driberg. Economic Stages of Development in Africa.  
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at 36 George Street, Manchester), at 7—Annual Meeting.

## SATURDAY, APRIL 16

- SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Zoology, University Museums, Oxford), at 10 A M and 2 30.

## Official Publications Received

## BRITISH

- Union of South Africa. Department of Mines and Industries. Geological Survey. The Geology of the Country south of Piet Retief, in Explanation of Sheet No 58 (Piet Retief). By Dr W A Humphrey and Dr L J Krige. Pp 72. (Pretoria Government Printing Office) 5s, including Map.  
Memoirs of the Geological Survey of India. Vol 57. Coal in India. 1. The Natural History of Indian Coal. By Dr Cyril S Fox. Pp vii+283+xxv+17 plates. (Calcutta Government of India Central Publication Branch) 9 4 rupees 15s 6d.

- Union of South Africa Department of Agriculture Science Bulletin 100 Bunchy Top Disease of Tomato By A P D McLean Pp 28+8 plates (Pretoria Government Printing Office) 3d
- Annual Report of the Indian Central Cotton Committee, Bombay, for the Year ending 31st August 1931 Pp ii+119 (Bombay G Claridge and Co., Ltd.) 2 rupees
- Memoirs of the Indian Meteorological Department Vol 25, Part 8 The Lunar Atmospheric Tide at Bombay (1873-1922) By Dr S K Pramanik Pp iv+279 289 (Calcutta Government of India Central Publication Branch) 10 annas, 1s
- The Journal of the Institution of Electrical Engineers Edited by P F Rowell Vol. 70, No 423, March Pp 297-392+xiv (London E and F N Spon, Ltd) 10s 6d
- Proceedings of the Malacological Society of London Edited by R Winckworth Vol 20, Part 1, March Pp 76+8 plates (London Dulau and Co., Ltd) 10s net
- City of Birmingham Education Committee The Value of Vocational Tests as aids to Choice of Employment Report of Research by E Patricia Allen and Percival Smith Pp vi+68 (Birmingham Education Committee) 1s net
- The Indian Forest Records Entomology Series, Vol 16, Part 10 New Species of *Exocentrus* Mulsant from India (Coleoptera Cerambycidae Subfamily Lamiinae) By W S Fisher Pp ii+31 (Calcutta Government of India Central Publication Branch) 7 annas, 9d
- Proceedings of the Nova Scotian Institute of Science Vol 18, 1930-1931, Part 1 Pp 21 (Halifax, N S)
- Archeologische Navorsing van die Nasionale Museum, Bloemfontein Deel 1, Stuk 2 4 2, Die Koningse Kultuur, n Die Verspreiding van die Koningse Industrie, deur Dr Ir E C N Van Hoepen, 3, Die Suid-Afrikaanse Klipwerktuie in Internasionale Verband, deur Dr Ir E C N Van Hoepen, 4, Die Mosselbaase Kultuur, deur Dr Ir E C N Van Hoepen Pp 13 54+plates 5-19 (Bloemfontein)
- Empire Marketing Board Preliminary Report on the Vitamin Content of the Mango By Edith O V Perry and Dr S S Zilva Pp 24 (London H M Stationery Office) 1s net
- Ministry of Health Advisory Committee on Nutrition Memorandum to the Minister of Health on The Criticism and Improvement of Diets Pp 14 3d net Report to the Minister of Health on Diets in Poor Law Children's Homes Pp 17 3d net (London H M Stationery Office)
- Department of Scientific and Industrial Research Building Science Abstracts Vol 5 (New Series), No 2, February Abstracts Nos 189 388 Pp 37 72 (London H M Stationery Office) 1s net
- Sight and Sound a Quarterly Review of Modern Aids to Learning Published under the Auspices of the British Institute of Adult Education Vol 1, No 1 Pp 30+xx (London British Institute of Adult Education) 1s
- Report of the Marlborough College Natural History Society for the Year ending Christmas, 1931 (No 80) Pp 81+4 plates (Marlborough)
- India Meteorological Department Scientific Notes Vol 4, No 3 A Study of the Structure of the Bay Storm of November 1926 By Dr Sobhag Mal and Dr B N Desai Pp 87-100+13 plates 2 2 rupees, 4s Vol 4, No 4 The Katabatic Winds of Poona By S Atmanathan Pp 101 115+2 plates 1 rupee, 1s 9d Vol 4, No 42 A Discussion of Monthly Mean Values of Upper Air Temperatures and Humidities obtained from Aeroplane Ascents at Peshawar and Quetta By A Narayanan Pp 125 136+3 plates 10 annas, 1s (Calcutta Government of India Central Publication Branch)

## FOREIGN

- Department of Agriculture, Straits Settlements and Federated Malay States Scientific Series, No 9 Hydnocarpus Oils in Malaya By C D V Georgi, Dr T A Buckley and Gunn Lay Teik Pp 18 (Kuala Lumpur) 50 cents
- Bernice P Bishop Museum Bulletin 83 New Plants from Fiji, II By John Wynn Gillespie Pp 72+1 plate Bulletin 84 Flora of Southeastern Polynesia 1 Monocotyledons By Forest B H Brown (Bayard Dominick Expedition, Publication No 20) Pp 194+35 plates Bulletin 85 The Land Snail Genus *Carelia* By C Montague Cooke, Jr Pp 97+18 plates Bulletin 86 Flora of Rarotonga By Gerrit Parmile Wilder Pp 113+8 plates Bulletin 87 Distribution and Variability of Ceratium in the Northern and Western Pacific By Anton Bohm Pp 46+1 plate Bulletin 88 Population and Utilization of Land and Sea in Hawaii, 1853 By John Wesley Coulter Pp 33 Bulletin 89 Flora of Southeastern Polynesia 2 Pteridophytes By Elizabeth D W Brown and Forest B H Brown (Bayard Dominick Expedition, Publication No 21) Pp 123+21 plates Bulletin 90 Houses, Boats and Fishing in the Society Islands By E S Craghill Handy Pp 111+25 plates Bulletin 91 New Plants from Fiji, II By John Wynn Gillespie Pp 81 (Honolulu, Hawaii)
- Memoirs of the Bernice P Bishop Museum Vol 11, No 5 The Fishes of Oceania, Supplement 1 By Henry W Fowler Pp 71 (Honolulu, Hawaii)
- Bernice P Bishop Museum Occasional Papers Vol 9, No 14 Additions to the Flora of Niuhau By Harold St John Pp 11 Vol 9, No 15 Geology of the Pacific Equatorial Islands By Chester K Wentworth (Whippoorwill Expedition Publication No 3) Pp 25 Vol 9, No 16 Mosses of Raiatea By Edwin B Bartram Pp 14 Vol 9, No 17 New Crustaceans from Kauai, Oahu and Maui By Charles Howard Edmondson Pp 18 (Honolulu, Hawaii)
- Bulletin of the National Research Council No 84 Report of the Committee on Hydrodynamics, Division of Physical Sciences, National Research Council Pp ii+634 4 50 dollars No 86 Bibliography of Bibliographies on Chemistry and Chemical Technology Second Supplement 1929-1931 Compiled by Clarence J West and D D Berolzheimer Pp 150 1 50 dollars (Washington, D C National Academy of Sciences)
- Smithsonian Institution United States National Museum Bulletin 157 The Butterflies of the District of Columbia and Vicinity By Austin H Clark Pp vii+337+64 plates (Washington, D C Government Printing Office)
- Physikalische Zeitschrift der Sowjetunion Herausgegeben vom Obersten Volkswirtschaftsrat der UdSSR Band 1, Heft 1 Pp 188 (Karkow) 15 rubel per year

- Proceedings of the California Academy of Sciences, Fourth Series Vol 20, No 9 Miscellaneous Studies in the Elateridae and related Families of Coleoptera By Edwin C Van Dyke Pp 291-465 (San Francisco) 1 dollar
- State of Illinois Department of Registration and Education Division of the Natural History Survey Bulletin, Vol 19, Article 5 The Plankton of the Sangamon River in the Summer of 1929 By Samuel Eddy Pp ii+469 485 Bulletin, Vol 19, Article 6 An Experimental and Observational Study of the Chumch Bug in relation to Climate and Weather By V E Shelford Pp iii+457-547 (Urbana, Ill)
- Proceedings of the Academy of Natural Sciences of Philadelphia, Vol 84 A Jamaican Fluvialite Nerita By Henry A Pilsbry Pp 11 14 The Land Snail Genus *Polygyrella* By Henry A Pilsbry Pp 15 19 (Philadelphia)
- Division of Fish and Game of California Fish Bulletin No 35 A Distributional List of the Species of Freshwater Fishes known to occur in California By Dr Barton Warren Evermann and Howard Walton Clark Pp 87 Fish Bulletin No 36 A Bibliography of the Sardines By Genevieve Corwin Wheeler (Contribution No 111 from the California State Fisheries Laboratory) Pp 135 (Terminal, Calif California State Fisheries Laboratory)
- Proceedings of the Imperial Academy Vol 8, No 1, January Pp 26 (Tokyo)
- Sveriges Geologiska Undersökning Ser Aa, No 172 Beskrivning till kartbladet Lugnas Av G Lundqvist, A Hogbom och A H Westergård Pp 185+1 tavl 4 00 kr Ser C, No 372 Diplocraterion, Monocraterion and Scolithus from the Lower Cambrian of Sweden By A H Westergård Pp 25+10 plates 2 00 kr (Stockholm P A Norstedt and Soner)
- Proceedings of the American Philosophical Society Vol 71, No 1 Pp 38 (Philadelphia)
- U S Department of the Interior Office of Education Bulletin, 1931, No 20 Biennial Survey of Education in the United States, 1928-1930 Chapter 6 Homemaking Education By Emeline S Whitcomb Pp 34 10 cents Pamphlet No 24 Salaries in Land Grant Universities and Colleges By John H McNeely Pp ii+27 5 cents (Washington, D C Government Printing Office)
- Agricultural Experiment Station of the Rhode Island State College Bulletin 233 Etiological Studies of Blackhead (Enterohepatitis) in Turkeys By John P Delaplane Pp 15 (Kingston, R I)
- Collection des travaux chimiques de Tchecoslovaquie Rédigée et publiée par E Votobek et J Heyrovský Année 4, No 2, Février Pp 49 96 (Prague Regia Societas Scientiarum Bohemica)
- Results of the Meteorological Observations in Työsen for the Lustrum, 1926-1930 Pp vi+56 (Zinsen Meteorological Observatory)
- Proceedings of the United States National Museum Vol 79, Art 29 The Buffalo Motive in Middle Celebes Decorative Design By Walter Hough (No 2895) Pp 8+9 plates Vol 79, Art 32 Excavations at a Prehistoric Indian Village Site in Mississippi By Henry B Collins, Jr (No 2898) Pp 32+13 plates Vol 80, Art 6 The Fishes obtained by the Pinchot South Seas Expedition of 1929, with Description of one New Genus and three New Species By Henry W Fowler (No 2908) Pp 16 Vol 80, Art 12 The Birds of St Lawrence Island, Bering Sea By Herbert Friedmann (No 2912) Pp 31+6 plates (Washington, D C Government Printing Office)
- Regenwaarnemingen in Nederlandsch-Indië Twee en vijftigste Jaargang, 1930 Pp ii+139 (Batavia Landsdrukkerij)
- Bulletin of the Geological Institution of the University of Upsala Vol 23 Pp iii+337+12 plates (Upsala Almqvist and Wiksels Boktryckeri A B)
- Memorias del Consejo Oceanográfico Iberoamericano Numero 6 Las posibilidades de un futuro desarrollo de la pesquera maritima en Chile Por Dr Hans Lubbert Pp 19 Numero 7 El volcanismo oceanico abismal Por J Thoulet (Madrid)
- Meddelelser om Grönland udgivne af Kommissionen for Videnskabelige Undersøgelser i Grönland Bd 79, Nr 1 The Godthaab Expedition 1928 Hydroids By P L Kramp Pp 86 Bd 91, Nr 3 Hydroids collected in West Greenland Fjords in 1911 and 1912 By P L Kramp Pp 35 (København C A Reitzels Forlag)
- University of California Publications in Archaeology and Ethnology Vol 29, No 4 The Patwin and their Neighbors By A L Kroeber Pp v+253 428 (Berkeley, Calif University of California Press) 1 60 dollars
- U S Department of the Interior Office of Education Bulletin, 1931, No 20 Biennial Survey of Education in the United States, 1928-1930 Chapter 5 Statistics of Teachers Colleges and Normal Schools, 1929-1930 Pp 78 15 cents Bulletin, 1931, No 20 Biennial Survey of Education in the United States, 1928-1930 Chapter 7 Statistics of Private High Schools and Academies, 1929-30 Pp 49 10 cents (Washington, D C Government Printing Office)
- Smithsonian Institution United States National Museum Bulletin 156 Aboriginal Indian Pottery of the Dominican Republic By Herbert W Krieger Pp iii+165+56 plates (Washington, D C Government Printing Office) 75 cents
- A Preliminary Study of the Ruins of Cobá, Quintana Roo, Mexico By J Eric Thompson, Harry E D Pollock, Jean Charlot (Publication No 424) Pp vii+213+18 plates (Washington, D C Carnegie Institution)
- Scientific Survey of Porto Rico and the Virgin Islands Vol 12, Part 1. Insects of Porto Rico and the Virgin Islands Heterocera or Moths (excepting the Noctuidae, Geometridae and Pyralidae) By W T M Forbes Pp 173+2 plates (New York New York Academy of Sciences)
- Smithsonian Miscellaneous Collections Vol 85, No 7 Effectiveness in Nature of the so called Protective Adaptations in the Animal Kingdom, chiefly as illustrated by the Food Habits of Nearctic Birds By W L McAtee (Publication 3125) Pp 201 (Washington, D C Smithsonian Institution)
- The Physical Laboratories of Harvard University Pp 47 (Cambridge, Mass)

## CATALOGUES

- Hair Hygrometers Pp 2 (London Negretti and Zambra)
- Floodlights on Photography Pp 16 (London Burroughs Wellcome and Co)

SATURDAY, APRIL 16, 1932

## Scientific Aspects of Fiscal Policy

IN a pamphlet entitled "The State and Industry in 1932", printed for private circulation, Capt Harold Macmillan, M P, elaborates further the scientific policy which should be the natural accompaniment of the British Government's general tariff plan and the creation of the Import Duties Advisory Committee (see NATURE, Feb 20, 1932, p 271). Capt Macmillan directs attention to the positive aspects of this new departure in fiscal policy, to the administrative problems which it presents, and to the vital importance that the opportunities under the new policy of securing the development of our industries on deliberately planned lines should be wisely, efficiently, and expeditiously used. The administrative methods adopted make the Import Duties Advisory Committee the keystone of the structure, and upon its efficient functioning depends the success of the whole policy. Altogether apart from the abilities of those chosen for this work, there is serious danger that the Committee may become a bottle-neck rather than an efficient clearing-house, resulting in delays exasperating to the applicants and endangering precariously situated industries, or in ill-considered judgments which will later bring discredit upon the Committee and upon the policy it is endeavouring to apply.

The execution of a constructive policy which is to be prospective and not merely retrospective involves the consideration by the Committee of many involved and highly technical problems on which it will require expert advice, and Capt Macmillan proceeds to discuss the methods by which such expert advice can be obtained from representatives of industry before blockage occurs and irreparable damage to public confidence has been done. In doing so, Capt Macmillan stresses the complexity of the economic problems involved and the high degree of social co-ordination required for their solution.

Scientific advance and large-scale production have so knit the nation into a compact unit that almost every question is now a national question and every action taken has its repercussions through the whole economic structure. While the field of Government responsibility is constantly increasing with every effort to deal with the acute problems arising out of changes in the balance and technique of production throughout the world, the close relation of those problems to industry involves increasing dangers from bureaucratic methods. Capt Macmillan sees in the existence of a National Government an opportunity of reviewing the whole

situation and avoiding a drift into future difficulties, by inquiring into the whole agenda of government and, if necessary, providing new machinery

To enable the Committee to exercise a guiding hand in the wider problems of reconstruction and to liberate it from detailed consideration of separate applications for additional duties, and at the same time to preserve industrial self-government, Capt Macmillan suggests as the necessary liaison with industry a representative Department of Industry or an industrial sub-parliament consisting of two or three representatives from national councils for industries or groups of industries. These representatives would be available for consultation by the Import Duties Advisory Committee in its efforts to reconcile the interests of producing and consuming industries where protective measures were under discussion, following the precedent of the Dyestuffs (Import Regulation) Act, and, if unsuccessful in reaching a satisfactory agreement, would enable the necessary information to be collected and the Committee to reach a rapid decision

This 'sub-parliament' would consider questions for the adequate discussion of which there is no present provision, including the displacement of labour through rationalisation, the balance of national production in the light of home requirements and export possibilities, the possibilities for the expansion of certain industries and provision for contraction of others, the conditions required for the development of new industries suitable to the country, the distribution of employment and its relation to housing, transport, road, water, gas, and electricity facilities, the gap between producers' and consumers' prices, the variation in wage rates between productive industries and sheltered services, the closer co-ordination of British financial organisation and British industry, the complementary development of British Empire production, the protection of any one industry from the high costs of inefficiency in another

These proposals, which thus envisage the co-ordination of national activity in the general interests of trade and industry, are rightly regarded as involving a functional system of representation, and on this ground alone would merit the attention of scientific workers. Although some skeleton organisation already exists in the Federation of British Industries and the Association of British Chemical Manufacturers, etc., which covers the ground to a limited extent for the chief industries of Great Britain, other industries are less effectively organised for the expression of representative views

The plea for the scientific examination of these

difficult questions, for the substitution of decisions based on ascertained facts instead of opinions which may or may not be prejudiced, and, above all, for the evolution of a definite plan on national lines to which sectional interests are subordinate, must command the sympathy of all scientific workers. Their support and help will be demanded in many ways if answers are to be found to the intricate technical and scientific questions involved, and if the evolution of a planned economy involves to some extent a transition to functional representation in parliament, it will undoubtedly indicate simultaneously ways in which the knowledge and training of the scientific expert can be more efficiently placed at the service of the community for the solution of the innumerable social, economic, political, and industrial problems in which vital scientific factors are involved.

### Social Economics

*The Work, Wealth and Happiness of Mankind.*

By H G Wells Pp xiii + 850 + 32 plates  
(London William Heinemann, Ltd, 1932)  
10s 6d net.

MR WELLS writes of himself "He is attempting a book, a survey of the world, a scheme and map of *doing*, which will enable him to say to anyone whatever 'This is the whole world of work and wealth, of making and getting and spending, and here at this point is your place, and this is where you come in. . . .'" Seeking Mr Wells's place in his own scheme, we find that he claims for his book the function of transmitting, correlating, and interpreting for the general mind the essential living thought of the world. In his "Outline of History" and "Science of Life" he attempted this task for history and for biology, now it is the turn of economics and sociology. Mr Wells holds that mankind's ideology, or system of ideas about life in general, has become dangerously out of date, and out of correspondence with the realities of human affairs, since the "change of scale", the "abolition of distance", of the last few decades. He regards as essential for a modern ideology some understanding of world history (as against local, national, and period history), some assimilation of biological ideas, and—most urgently necessary of all—some conception of economic life, industrial processes, trade, and finance. Valiantly he has attempted to supply all three sides of this ideological triangle, and his third compendium, like its forerunners, is a remarkable, stimulating, valuable, and most readable book.

In the development of a modern ideology, the first step, says Mr Wells, is to learn to think. "Most of us do not think enough about thinking" Children and primitive peoples do a large part of their thinking by imagination, their thinking is a spontaneous, uncontrolled flow of images, with which impulses to act are connected. There is no critical element, and scarcely any use of generalisations or abstract ideas. Things not themselves physically real are apprehended in a symbolical and often a personified form. The thinking of many adults is still of this kind, corresponding to what has been called the 'mythological' phase of human development. This was followed by the gradual appearance of exacter discrimination, the mythological passed insensibly into the metaphorical, abstraction became possible, classification and examination of ideas began, and 'logical' thinking followed.

"This change from a mental life that was merely experience-checked imagining to an analytical mental life aiming at new and better knowledge and leading on to planned and directed effort, is still in progress. Over a large range of his interests man has still to acquire the habit of thinking with self-control and precision." "The man who orders his knowledge and thinks things out is as far above the natural man of impulse and traditional usage as the latter is above an ape which has not even tradition but only instinct."

Logical thinking, however, contains in itself a pitfall. Are words as true as material facts, or truer, or less true? If they are truer, then a logical conclusion is truer than an experience, and that, on the whole, was the 'Realist' assumption of classical and medieval times, the view that classes or Platonic ideas were the only reality, the view which nowadays is sometimes loosely called 'Idealism'. Realism was opposed by the 'Nominalist', for whom an experience is truer than a word. The defeat of philosophical Realism over large areas of human interest in the late Middle Ages and after was a necessary preliminary to the release of experimental science, and to the material triumphs following on the application of the scientific method of 'trying back to facts' all the time.

"The discovery of Evolution, the realisation, that is to say, that there are no strict limits set to animal and vegetable species, opened the whole world of life and its destiny to Nominalist thinking. The realisation by the world of mathematical physics that the universe can be represented as a four-dimensional universe of unique events has abolished the conception of a quantitative equivalence of cause and effect and made every atom unique."

The detachment of logical thinking from the Realist predispositions of the human mind remains, however, incomplete, and in the world of international politics the Realist way of thinking holds almost undisputed sway and lies at the root of the greatest dangers that threaten our race.

"Plainly a man who takes the Nominalist way and regards such a word as 'France' as merely covering a great area of country, climatic and social associations, and about forty million human beings of very diverse kinds (numbers of them not even speaking French) will regard international politics from an entirely different angle from a Realist who finds in the word France something more real and vital than any single individual or thing that contributes to the ensemble of that idea. The Nominalist and Realist of contemporary life, all unaware of this difference in the very elements of their thought, find each the other stupefyingly obtuse. The Realist 'patriot' calls his brother Nominalist 'traitor' or 'cosmopolitan scoundrel', and the like, and is amazed that he does not wince; the Nominalist humanitarian calls the Realist, obdurate dogmatist or romanticist, and accuses him of a perverse taste for contention and blood."

Mr Wells, then, would have mankind abandon emotional for logical thinking, and in logical thinking beware of 'Realist' assumptions and remember the fruitfulness of the scientific appeal to fact. His early chapters recite some of the practical triumphs of science, the conquest of materials—iron and steel, rubber, petroleum, dyes, drugs, cellulose—the conquest of power, the organisation of transport, the transmission of facts, the application of artificial fertilisers and mechanical methods to agriculture, all the modern developments in the feeding and clothing and housing of mankind. He discusses the ways in which work is organised, and then turns aside to inquire why people work. He divides mankind into three classes, according to their guiding idea of themselves, or "persona": the "peasant", characterised by the idea that toil is virtue, and by intense acquisitiveness, the "aggressive nomad", generous, reckless, and rapacious, and the "educated" man, originally priestly in function, who works not for his own enrichment, or for his own honour and glory, but is devoted to some end transcending personal considerations. With the peasant type and derived from it, Mr Wells places the peasant-minded townsman, giving rise on one hand to a crop of "petty" and "big bourgeois", and on the other to a multitude of "expropriated" proletarians who have lost their grip upon property.

The peasant persona and its modifications will tend to cause the possessor to work for personal

gain, the nomad persona for personal glory, the educated persona for some ideal of service. Mr Wells denies the Individualist creed that the peasant-craving for tangible property generally is a fundamental incentive to work. "The human animal wants a feeling of security and it wants freedom and the feeling of power. These wants are truly fundamental." The experience of the educated types shows, he thinks, that the satisfaction of these desires can be guaranteed in quite other ways than by the actual possession of land, wife, children, goods, and chattels. With the extension of literacy, the mentality of the learned clerk begins to penetrate everywhere, carrying its traditional disposition to find the satisfaction of good achievement greater than the satisfaction of possessions. The search for security, comfort, and liberty becomes the ruling motive in keeping mankind busy.

Mr Wells pauses to note a common confusion between independence and liberty. "Independence is no doubt being abolished in the case of individuals just as in the case of sovereign states, but independence is not freedom. An 'independent' peasant or small tradesman is tied, with scarcely a day's holiday, to his cultivation or his shop." But the worker under modern conditions has real personal freedom in the way of daily leisure, holidays, choice of activities and purchases. To provide such modern satisfactions, and to free himself from tangible burdensome ownership, man has made use of the abstraction of a monetary system. Mr Wells discusses currency, financial methods, banking, and investment, and gives an account of the world depression with the monetary factors well emphasised. He describes recent proposals for monetary reform, indicating here, as in many other parts of the book, the imperative need for international action.

The closing chapters bring him again to education, and to his reiterated thesis that a civilised World State can only develop in correlation with the spread of the 'educated' persona, with the replacement of the motives of profit and privilege by the motive of service in affairs of every kind. Such a co-operative outlook has become essential, nothing less than world planning for political and economic change can avert disaster. Mr Wells is optimistic enough to believe in the necessary educability of mankind, for is not educability the main distinguishing characteristic of *Homo sapiens*?

If "The Work, Wealth and Happiness of Mankind" is not on the whole as satisfactory as the "Outline of History" or the "Science of Life",

the defect is probably inherent in the less developed state of economic science as compared with history or biology, and perhaps also in our more primitive type of thought on economic subjects. One misses those diagrams and tables which were so useful a feature of the two earlier books, and which are replaced by a few casually selected photographs in the present volume. Yet Mr Wells has given us what is likely to remain for a long time the most comprehensive and lucid account available of the tangled complexity of economic processes in their human aspect, and the ways in which those processes are affected by the decisions we all have to make.

### A Survey of Radioactivity

*Lehrbuch der Radioaktivität* Von Georg v. Hevesy und Fritz Paneth. Zweite, völlig umgearbeitete Auflage. Pp. xii + 287. (Leipzig: Johann Ambrosius Barth, 1931.)

THIS book was first published in 1923 and immediately found an appreciative public on the Continent. It became more widely known to British and American readers in 1926 when it was brought up to date and translated. That edition was reviewed in these pages at the time (see NATURE for Oct. 2, 1926, p. 475).

The work has now been thoroughly rewritten, revised, and enlarged to embrace the more important advances made in the subject since 1923. It takes new matter forms about a quarter of the present book. It deals with such subjects as the radioactivity of potassium and rubidium, the 'packing effect', the structure of the nucleus, the distribution of electrons in atoms, the origin of the actinium series, and the interpretation of the facts of radioactivity on the new quantum mechanics.

The data of radioactivity have been brought up to date and given accurately. In one or two cases where constants have different values from those given in "Radiations from Radioactive Substances", they are those approved by the International Radium Standard Committee, the report of which appeared recently. They give the half-value period of the potassium isotope of mass 41 as  $7.5 \times 10^{11}$  years on the assumption, indicated by the experimental work of the senior author, that this mass is responsible for all the  $\beta$ -particles emitted. They follow Lord Rutherford and Dr. F. W. Aston in deriving the actinium series from a uranium isotope of mass 235. This is, of course, the right thing to do at present, since there is little or no doubt that the series ends on the mass actinium-D,

207, but a series of products, the masses of some of which are of odd number, may not have the simplicity of the thorium and radium series, where the only massive particle expelled is the  $\alpha$ -particle. There is a possibility that another massive particle is expelled. The final work of Dr F W Aston on the complexity of uranium should be an important contribution to this interesting problem. In the tables of isotopes and elements the new isotopes of carbon, nitrogen, and oxygen found by American workers are included, but nothing is said about elements 61, 85, and 87, except that they are still undiscovered.

This new edition has had the great advantage of being revised after the publication of the authoritative work of Lord Rutherford, J Chadwick, and C D Ellis. Its authors have succeeded in making it an informative, critical, and accurate textbook, covering not only the physical side of the subject with its many topics, but also the chemical and geological sides. It is wider in scope than the larger and more learned treatises. It is clearly written, and the text gains much from the fifty figures and nearly fifty tables which accompany it. It should be on the shelves of every physicist and inorganic chemist reading German who wishes a general, as opposed to a highly specialised, knowledge of this interesting range of subjects.

### The Migratory Impulse of Birds

*The Riddle of Migration* By William Rowan  
Pp xiv + 151 (Baltimore, Md. The Williams  
and Wilkins Co., London. Baillière, Tindall  
and Cox, 1931) 11s 6d net

THE author of this book is professor of zoology in the University of Alberta and he has most courageously undertaken the experimental study of the causes of the migration of birds. Some most astounding facts—experimental and observational—are recorded in his book. Edmonton, the city in which the University is situated, has wonderful advantages for this study. The tremendous contrast between the seasons in Canada compels practically all the birds to migrate. The minimum temperature in winter may drop to  $-52^{\circ}\text{F}$ , whilst the summer temperature may rise to  $100^{\circ}$ . Then to the north an unbroken plain stretches to the shores of the Arctic Ocean, whilst to the south-east a similar plain reaches the Gulf of Mexico, so that the physical obstacles to migration are slight.

Preliminary observations had suggested to

Prof Rowan the theory that the impulse to migration might arise from the swelling genital organs, and accordingly he selected a common native bird, the junco sparrow, as the subject of his experiments. This bird has about the size and appearance of the ordinary British sparrow, but it is at once distinguished from our sparrow by the white colour of its under-side and of the outer tail-feathers. A number of juncos were confined in a large cage and subjected to the influence of a powerful electric light for periods approximating to the length of a summer day until the winter solstice, whilst an equal number of controls in another cage experienced the gradually decreasing hours of daylight. Both cages were unheated. The gonads of the controls shrunk in size until at Christmas time they were mere shrivelled rudiments, whilst those of the illuminated birds grew in size and by January had attained almost their maximum development. Further, whilst the control birds remained inactive and were silent, the illuminated birds were in full song in the middle of winter.

The mode of action of the light was next considered. Was its action direct or did it act by keeping the bird in a high state of vitality? The answer to this question was found by keeping two sets of juncos in practical darkness, broken only by the glimmer of electric 'night-lights'. In one cage the controls were kept, whilst in the other an ingenious arrangement of moving perches was installed so that the birds had to keep hopping up and down. These birds developed large gonads in spite of the darkness and the cold.

We may say that this result of Prof Rowan's is confirmed by the experience of poultry-breeders in eastern Canada. 'Christmas eggs' were notoriously difficult to obtain in Canada, and their price used to reach fantastic heights. The old practice was to keep the birds in closed hutches heated by oil lamps. They became comatose in winter and refused to lay. Then the experiment was made of keeping them in hutches sheltered above but open below to the ingress of fresh air, and entirely unheated. The grain given as food was mixed with bran and sawdust, so that the birds had to kick and scratch vigorously to find it. These birds continued to lay eggs all through the winter.

It is therefore established that the impulse to migrate northward in the spring is called forth by swelling gonads. But how do the birds find their way over such enormous distances? According to the author, the Pacific plover annually migrates from British Columbia to Hawaii over two thousand

miles of sea, the golden plovers winter in Mexico and Central America, and when, after finishing their breeding, they return to their winter homes, the adults go through the eastern States and even over the sea, whilst the young leave after the adults and fly directly south through the central plains

Only two plausible explanations of migration have ever been put forward (1) that it is due to tradition and memory, (2) that it is the result of inherited habit Prof Rowan suggests that quite possibly the first explanation will hold for the movement of the older birds, since there is a rich harvest of autumn berries to be found on the east coast, but only the second will avail to account for the migration of the young birds, since they have never been south before Prof. Rowan pathetically remarks that this second explanation has a dangerous resemblance to Lamarckism, and that although no one has disproved Lamarckism, yet all the most elaborate experiments designed to test Lamarckism have given a negative result

Prof Rowan may take heart the elaborate experiments referred to—presumably Weismann's attempts to show that the mutilation of the tail is not inherited in mice, Brown-Sequard's assertion that epilepsy in mice induced by spinal section was transferred to offspring, etc—were planned to prove something which Lamarck himself would have utterly repudiated Lamarck says, "But whatever environment may do, it does not work any direct modification in the shape and organisation of animals, but great alterations in the environment of animals lead to great alterations in their needs, and these alterations in their needs lead to others in their activities Now if the new needs become permanent, the animals adopt new *habits* which last as long as the needs which evoked them All these are preserved by reproduction to the new individuals which arise" An 'acquired character', therefore, according to Lamarck, is an acquired habit, and if Prof. Rowan will look into the matter he will find that there is abundant experimental evidence for the effect of acquired habits on the next generation—not in the sense that the young retain in full force a habit acquired by the parent in a different environment, but that the young exhibit a trace of the parental habit, a trace which can be strengthened by constant repetition

Prof. Rowan is at present engaged in testing whether his birds forced into sexual maturity during the winter will migrate if released, and, if so, in what direction. The control of this experiment

is obviously extremely difficult, owing to the wide field open to the migrants and the difficulty of recapturing the migrants At the time of writing his book little progress had been made, but we understand that since that time Prof Rowan has had more success, and we look forward with interest to the appearance of a second edition of his book

### Psychic Sounds

*On the Edge of the Etheric being an Investigation of Psychic Phenomena based on a series of Sitzings with Mr John C Sloan, the Glasgow Trance and Direct Voice Medium* By J Arthur Findlay. Fifth impression Pp 177 (London Rider and Co, 1932) 3s 6d net

THIS volume, which has reached its fifth impression in four months, is the record of a series of sittings with a Scottish 'direct-voice' medium The author, who during his residence in Glasgow was a well-known business man, was fortunate in having secured a considerable number of sittings with this medium—an ordinary working man, by name John C Sloan—who is said to possess the most marvellous powers Not only is he clairvoyant and clairaudient, whatever these terms may mean, but also in his presence, and generally in darkness, voices are heard which purport to be those of deceased persons, voices which are recognised by their friends and relatives still alive, and give striking evidence of identity

Mr Findlay is of opinion that Mr Sloan is certainly not normally responsible for these voices, and he has come to the conclusion that they are what they purport to be, the spirits borrowing material wherewith to form some kind of materialised 'mask' in the likeness of a mouth and throat with which they make intelligible sounds This borrowed substance is alleged to be taken from the medium and sitters, and is then manipulated by the unseen entities for the purpose for which it is intended Although Mr Findlay claims to be interested in physics, and therefore, presumably, in scientific work, he appears to have made no experiments to test this remarkable phenomenon, concentrating his attention upon the evidence given by the voices in support of their claims, and, even more oddly, upon the information vouchsafed by the spirits regarding their surroundings Much of this material seems clearly derived from popular manuals dealing with the supposed 'etheric' body, and a good deal of it is directly traceable to spiritualistic literature having a wide circulation

The book is typical of many that are being published to-day. No one can deny that the phenomena, as they are described, are puzzling, and, if independent examination confirmed the account here printed, are worthy of the closest scientific scrutiny. But from reading Mr Findlay's records, the scientific method might be thought not to exist. He seems to have no appreciation of the implications underlying many of his remarks, no desire to see the phenomena described in accurate and scientific terminology. The explanations given by the spirits (who include, it may be added, Huxley, Faraday, and Wallace) are just what would be expected from a man who had read the works of Lodge, Crawford, and Schrenck-Notzing, and had combined scraps of each for his purposes. As explanations, they are worthless. As suggestive of human origins, they are significant.

### Short Reviews

(1) *International Address Book of Botanists being a Directory of Individuals and Scientific Institutions, Universities, Societies, etc., in all parts of the World interested in the Study of Botany*. Prepared in accordance with a Resolution passed at the Fifth International Botanical Congress, Cambridge, 1930. Published for the Bentham Trustees. Pp xv + 605. (London: Baillière, Tindall and Cox, 1931.) 12s 6d net.

(2) *A Biographical Index of deceased British and Irish Botanists*. Compiled by James Britten and George S. Boulger. Second edition, revised and completed by Dr A. B. Rendle. Pp xxii + 342. (London: Taylor and Francis, 1931.) n.p.

(1) At the Fifth International Botanical Congress held at Cambridge in 1930, the necessity for a new address book of botanists of the world was emphasised and an International Committee was appointed to make all arrangements for the publication of such a book. The Committee consisted of Prof L. Diels (Berlin), Dr E. D. Merrill (New York) and Major T. F. Chipp (London). After Major Chipp's untimely death in 1931, his share of the work was carried on by Miss M. Verbrugge. This volume is the result of the splendid effort of the Committee. Realising that it would be impossible to incorporate all available information in a compact volume of useful size, the compilers have made a wise choice of material and given such facts as they decided would be most sought after.

The arrangement is by countries alphabetically. The entries in each country include botanical societies, institutions (wholly or chiefly botanical), educational institutions having botanical departments, and an alphabetical list of professional and amateur botanists with their offices, qualifications, addresses, and special botanical interests.

It is certain that this book will prove invaluable to botanists throughout the world.

(2) Though the title would scarcely suggest it,

this book has proved very useful to botanists in the past, thus calling for a second edition. The compilers have been liberal in their choice of names to be included in the list, though nothing is redundant. The names are arranged alphabetically and are followed by dates of birth and death (in most cases place of burial has been omitted in the second edition), position and occupation, titles and degrees, dates of election to the Linnean and Royal Societies, reference to botanical work, portraits, and genus or species dedicated to the person in question.

The information, brought together in 342 pages, should be of great use to botanists in general, and especially to British botanists.

*A Handbook of the British Seaweeds*. By Prof. Lily Newton. Pp xiii + 478. (London: British Museum (Natural History), 1931.)

In order to fill the gap in botanical literature left by the absence of any up-to-date account of the British seaweeds, Dr A. B. Rendle, formerly keeper of the Department of Botany of the British Museum, arranged with Dr L. Batten, now Prof. Newton, to prepare this handbook. The basis of the arrangement is the "Catalogue of the British Marine Algae", by E. A. L. Batters, which has long been out of print. In all, about 260 genera and 750 species are described. The drawings were mostly made by the late Mr Percy Highley, though some are by Prof. Newton. The aid of members of the staff of the Department of Botany of the British Museum is freely acknowledged, thanks being especially due to Mr G. Tandy for his help on the taxonomy and nomenclature. This very useful book starts with an account of methods of collection, preservation, and of the distribution and ecological relationships of algae. An outline of the classification is given, also some data on economic uses. It may be remarked that the account of the preparation of iodine from kelp sounds like a translation from the German, and, according to the construction of the English, is incorrect.

The book should prove a great stimulus to the further study of this branch of botany, which has been neglected in Great Britain so long. Those who studied this branch of botany a few years ago cannot help being somewhat puzzled by the numerous changes in names, thus even our old friend *Fucus platycarpus* has disappeared and is not even mentioned as a synonym. The work appears to have been carried out with the care which one would expect, considering its origin. The illustrations have been well done, and the whole book can be heartily recommended.

*Handbook of Protozoology*. By Prof. R. R. Kudo. Pp vii + 451. (London: Baillière, Tindall and Cox, 1931.) 25s net.

NUMEROUS excellent textbooks of protozoology have already been published and at first sight it might seem that to add another to the list was superfluous, yet, as the author of the present one points out, most of the modern publications emphasise the parasitic forms and do not give much space to the

taxonomy and biology of the free living forms, from which the parasitic groups were undoubtedly derived

The book is divided into two parts, the first consisting of chapters devoted to the general morphology of Protozoa and, though briefly treated, gives the student a good elementary knowledge of the principles of protozoan structure and physiology. The second and more important section of the book is concerned with the taxonomy and general biology of the different groups of common Protozoa. This is probably the more useful section of the work, for, owing to the numerous comprehensive and widely scattered monographs that have appeared on the different groups, it is often difficult for the average student to obtain all the necessary literature.

The author, by gathering together in a limited space as much of such material as possible from various authorities, has rendered good service, and the book should prove valuable to teachers in universities—but perhaps more particularly to those engaged in applied biological science who are cut off from libraries but desire to identify the organisms found in their several fields of research.

*Die Insektenfauna des Bottlinger Marmors eine systematische und palaobiologische Studie* Von Dr Friedrich Zeuner (Fortschritte der Geologie und Palaontologie, herausgegeben von Prof Dr W Soergel, Band 9, Heft 28) Pp viii + 247-406 + 19 Tafeln (Berlin: Gebrüder Borntraeger, 1931) 25 gold marks

THE Bottlinger marble fills a fissure 10 metres wide and 400 metres long at the margin of a crater of Upper Miocene age near Munsingen in Swabia. In Upper Miocene times hot carbonated waters flowed up the fissure and deposited calcareous sinter within it. A varied insect life abounded in the bushes and grasses surrounding the well. Individuals of this fauna, venturing too near the fatal waters, were killed, their bodies fell into the well and were quickly encrusted with sinter. A swarm of bees was entombed in this manner. Thus was provided the beautiful material studied by Dr Zeuner, who gives a lively picture of conditions around this Upper Miocene poison hole.

Dr Zeuner describes in detail the insect fauna of this well, making four new genera and eleven new species. He discusses the phylogeny of the Upper Miocene insect faunas and the climate of the time. He concludes that the climate of separate periods of the Tertiary cannot be deduced independently from insect faunas, since many groups have changed their habitats since the Tertiary. Harrassowitz came to a similar conclusion in connexion with Tertiary floras.

*Physiography of Western United States* By Prof Nevin M Fenneman Pp xiii + 534 (New York: McGraw-Hill Book Co., Inc., London: McGraw-Hill Publishing Co., Ltd., 1931) 25s net

THE central theme of this book is geological rather than geographical. It treats land forms, which are its main concern, as effects and not as causes. Nevertheless, it will be of value to the geographer

as well as the geologist, for it gives accurate descriptions of the topography, with special stress on the drainage systems. The area covered lies approximately between long 100° W and the Pacific coast, and the treatment is by natural physical units called provinces and sections. These, as determined by the Association of American Geographers and United States Geological Survey, are shown on a large folding map which accompanies the volume. This useful map has also been separately published as an official American map.

The volume is clearly written and well arranged, though, of course, the treatment of different areas depends on the knowledge available. In a few parts little more than a description of the surface topography can be given. The many illustrations and block diagrams, and above all the copious bibliographical references, add to the value of the book. A companion volume on the Eastern United States is announced to be in hand.

*Botany for Matriculation* By Dr F Cavers Revised by L C Fox Second edition Pp viii + 509 (London: University Tutorial Press, Ltd., 1931) 6s 6d

To any candidate for university matriculation who is studying 'privately' with the view of matriculating only, and no ultimate aim of assuming an interest in, or attaining a sound knowledge of the science of botany, "*Botany for Matriculation*" is to be recommended. Such an opinion is offered to such 'private' students only, for we would prefer to leave the choice between a stimulating book and a 'cram' book to the teachers of other students.

The book begins, as it ends, with bald statements of fact and theory. It is profusely illustrated with diagrams fit to reproduce before an undiscerning examiner, but serving no other purpose. The subject matter has apparently been chosen to conform to the average matriculation syllabus. At the end of each chapter, a set of questions are given, in one case, the set of twenty-four questions contains sixteen which begin with the word 'Describe', and this is more or less the ratio throughout. L J F B

*Recent Advances in the Study of the Psychoneuroses.* By Dr Millais Culpin (The Recent Advances Series) Pp vii + 348 (London: J and A Churchill, 1931) 12s 6d

THE study of the psychoneuroses, or, as Dr Culpin sometimes prefers to call them, the minor psychoses, is a peculiarly wide and difficult subject. Dr Culpin in this book gives a very compact and readable account which well maintains the standard set in this series. The book is written from the point of view of psychoanalysis, that is, a strictly Freudian attitude. The views of Jung and Adler are well set out in separate chapters by Dr Young and Dr Redfern. Dr E Miller deals with the psychopathology of childhood and Dr Rees with psychotherapeutic clinics. While stressing the Freudian approach, the author is careful to maintain an even balance, so that the physical side of the picture is by no means neglected.

## Flame Movements in Gaseous Explosions

PROF. W. A. BONE and Mr. R. P. Fraser have recently described their further experiments upon detonation of combustible gaseous mixtures.\* Some very beautiful photographs of the phenomenon of 'spin', first observed by Campbell and Woodward (1926), have been taken by means of

explosive detonator. Ignition could also be brought about farther down the tube, either by a spark or by means of a detonator which provided a shock wave in nitrogen contained in the first part of the tube. Depending on the strength of the detonator, the shock wave could either be allowed to follow the explosion flame, to catch it up, to proceed with the same speed, or to pass through it: it was shown that in the latter case the shock wave could initiate flame in the gas mixture ahead of the flame front, as is shown in Fig. 1. The flame is here travelling in the direction left to right, and the photographic paper moving rapidly in the upward direction at right angles to the direction of the flame. The sudden acceleration of the flame when the com-

the Fraser high speed camera, especially designed for this work, and described in *Phil. Trans.*, vol. 228, 1929, p. 197. The larger machine was able to provide a vertical peripheral film speed up to 200 metres per second, so that resolution of the high speed movements of the flame front is obtainable.

Explosion of the gas mixtures in the long glass tubes was initiated either by a spark or by a high

FIG. 2.—Spiral path of detonation in 2CO : O<sub>2</sub> mixture.

pression wave passes through it, and the subsequent ignition ahead of the compression wave prior to the arrival of the flame front, are clearly shown. The detonation wave can be seen travelling back through the burning gases, where the original flame front meets the auto-ignited flame. Impact of the shock wave on an advancing flame does not necessarily lead to detonation, but if the shock wave is sufficiently powerful, detonation is set up; it can even be caused to occur in this way close to the initiating spark. Prof. Bone and Mr. Fraser have confirmed that the velocity of the detonation wave during the early part of its course is more rapid than the subsequent uniform rate to which it settles down.

Part vi. of the paper deals with the phenomenon of spin already mentioned, which is well illustrated (Fig. 2). The flame does not appear to travel axially down the tube in the forward direction, but takes a spiral path: not only is this the case for the detonation wave, but also in some cases the phenomenon is observable in the advancing flame prior to detonation. Bands are visible in the gaseous

\* Photographic Investigation of Flame Movements in Gaseous Explosions, Parts iv., v., and vi., *Phil. Trans.*, vol. 230, p. 363.

products behind the flame, which have a frequency connected with the rotation of the 'head' of detonation—frequencies of more than 100,000 a second being sometimes observed. The distance traversed per second by the head of detonation along its spiral path is constant in a given gas mixture, and the ratio of pitch to the diameter of tube is nearly constant, but in some cases two or more rotating 'heads' of detonation are observable.

In the initial stages of an explosion the gaseous medium is moved forward along the direction of the tube axis: this forward impulsive motion would set up rotation about lines which may roughly be described as circles on a plane perpendicular to the axis and with centres approximately on it, and if

this were superposed on an axial rotation a spiral vortex system would be initiated. Whether an explanation on this basis can be derived, or whether the rapid agitation of molecules through the gaseous medium sets up a disturbance along the axis, changing to a spiral wave front or 'head' which in turn gives rise to periodic waves in the 'tail' behind, are matters which are to be the subject of further investigations. Thirty-four photographs which Prof. Bone and Mr. Fraser have presented in their paper afford very considerable food for thought, and no such remarkable records of the behaviour of rapid flame motion have been published since those in Prof. H. B. Dixon's memoir in the *Phil. Trans.* of 1903. A. C. E.

### Screen-Plate Colour Photography

THE two great lines of attack on the problem of colour photography are undoubtedly comprised in the 'subtractive' processes on one hand and the 'screen-plate' processes on the other. In spite of the initial simplicity of negative-making in the subtractive process and the application to three-colour work in commercial printing, the production of the following 'positive' colour pictures by the amateur is still a matter requiring some experience, skill, and patience. Although undoubted progress has been made, the results are not of a very certain character, and they are hard to control in any precise manner.

On the other hand, the 'screen-plate' processes are of a nature much more amenable to precise control. Their disadvantage, if it be a disadvantage, is that the immediate result is a transparency rather than a picture on paper; and the transparency cannot be seen to advantage without some care in its illumination or without the use of projection apparatus. We may, however, remark that the reason why so many amateurs nowadays are dissatisfied with their photographs is because the *viewing* of photographs has never received a tithe of the attention which has been so lavishly given to their taking. A small print made with a 4-inch lens is viewed from a distance of twelve or fifteen inches. The result is a false rendering of the perspective and a general impression of an insignificant little picture. If the same photograph is printed as a transparency and viewed under proper illumination with a lens of 4-inch focal length, the perspective is seen under the proper angle and the result is vastly more satisfying and impressive. The projection of the picture is an equally good alternative.

The present writer has tried in vain to convince manufacturers upon this point, but if those who produce colour transparencies take the matter to heart they are not likely to tire of their pictures, even those made on a very small scale. Properly viewed or projected, transparencies have a wealth of beauty and satisfaction to give as compared with the finest pictures on paper.

The well-known Autochrome and Agfa plates have the colour mosaic incorporated in the first

layer underneath the sensitive emulsion, and the positive picture is obtained by photographic 'reversal' of the negative obtained by exposure through the mosaic. The alternative procedure uses a colour screen printed separately on another plate of glass, the screen surface being held in contact with the emulsion of a panchromatic plate during the exposure. The negative resulting on development is printed as a positive and can then be bound up with a 'viewing screen' containing a corresponding mosaic; details are generally given in articles on colour photography. In this way, any number of copies can be made.

Examples of such processes were the Joly screen plate ruled in lines, and dating from 1904, and the plates developed by Mr. C. L. Finlay, which have been embodied in the 'Thames' and 'Paget' plates. The modern form is being marketed as the 'Finlay' process.

The progress made by photographic plate manufacturers has rendered possible corresponding progress in colour photography, since it is vitally dependent on satisfactory panchromatic emulsions. An Ilford panchromatic plate (700 H and D) is specially coated for the Finlay process, and a series of five carefully adjusted compensating filters is available for use with different conditions of natural and artificial lighting. The high speed of the plates allows of snapshot exposures under favourable lighting conditions if a lens working at an aperture of  $f/4.5$ , or thereabouts, is used.

The 'taking screen' with its mosaic of squares is printed by a secret process, but it is being claimed by the makers that a system of efficient inspection of the plates, and standardisation of the dyes, has enabled them to eliminate the variability which used to be experienced sometimes in the older types of plates. Methods of measurement of colour for microscopic objects are now easily available, and the efficient standardisation of the taking screens, filters, and viewing screens ought to be possible.

This is a matter of the very greatest importance for the technical use of the process in cases where pictorial colour records are required. The use of such records in microscopy, surgery, medical research, metallurgy, and other subjects would be

legion. It is impossible with a three-colour screen to make the photograph an absolutely exact rendering of the original visual impression, but it would be a great step to have a genuinely reproducible action, so that a definite colour difference occurring, say, in two photographs (taken at an interval) of a case of skin disease would have to be ascribed to an actual colour change in the object. This kind of reproducibility may be within the reach of really rigid standardisation, but this applies equally to the user's end of the business, where proper attention will be necessary in exposure, time and temperature of development and so on.

The use of a separate positive and viewing screen has now been superseded by the Finlay positive colour screen made by coating a viewing screen with a positive emulsion. Very careful registration is naturally necessary before the positive is printed, but the special system adopted in the process allows this to be done satisfactorily. The result is a picture entirely free from colour changes depending on the angle of view. It is easily understood that, granted the registration is exact, the disappearance of the parallax between the positive and the screen will result in the elimination of diffusion between the edges of the corresponding square elements in the two layers and a consequent improvement of the 'saturation' of the colour rendering. It is claimed by the makers that these plates can be used effectively for reproduction purposes for half-tone work.

Of course, the chief difficulty in making half-tone blocks from screen plates with a regular pattern has been that the pattern of the screen plate is likely to clash with that of the half-tone screen and produce moiré effects. This difficulty can, however, be overcome by placing the lines of the two screens at a suitable relative angle, and using a very slight softening of the focus, it is a matter calling for some care and skill.

Development work recently in progress has been concerned with a screen-plate for photographic reversal, the application of the colour screen to kinematograph film, and the adaptation of a modified collotype process to the production of colour prints on paper, starting from the original screen-plate record. It is also claimed that it is now possible to reproduce the Finlay pictures in colour by colour gravure, collotype, and by photolitho offset. Many interesting and excellent pictures have been made for exhibition by these various processes.

In spite of difficulties and discouragements it seems that this screen-plate process should find an increasing sphere of interest and utility. Success will be the reward of a steady improvement and standardisation of the materials, and of persistent investigation of the various possibilities of the process in printing, in amateur and professional photography, and in science, but the experience of the last twenty years indicates that progress can best be made by persistent expansion from modest beginnings. L. C. M.

### Industrial Bursaries\*

IN articles in NATURE nearly two years ago (June 21 and 28, 1930), the late Sir Francis Ogilvie gave an interesting account of the development and work of the Royal Commission for the Exhibition of 1851.

At that date the Commissioners had just published the Record of their Science Research Scholars, of whom the first was appointed in 1891. The Record of their Industrial Bursars, now issued, tells of a more recent branch of that work, only just alluded to by Sir Francis Ogilvie, to whose help much of its success has been due. It affords further evidence, should that be needed, of the far-reaching extent and valuable results of the activities of the Commission.

Founded in 1851 to administer the surplus funds of the Exhibition, the Commissioners have for eighty years employed their resources generally in accordance with the lines laid down by the Prince Consort. "For its application", he wrote in the autumn of that year to Baron Stockmar, "I have devised a plan", and to this plan, with such minor modifications as changing times demanded, they have adhered. It has been their object to assist in the establishment of institutions which, in the words of their Supplemental Charter, "might increase the means of Industrial Education and extend the influence of Science and Art upon productive industry".

\* The Record of the Industrial Bursars of the Royal Commission for the Exhibition of 1851, 1911-1929. Published by the Commission, 1 Lowther Gardens, Exhibition Road, S.W. 7.

In 1911 the Science Scholarships had been established for twenty years, and their value was generally recognised. They had opened a scientific career to students from all parts of the Empire, and the results achieved by those students were even then of marked importance. Now forty of their scholars are on the roll of the Royal Society.

Among the means whereby improvement and progress can be obtained in any branch of knowledge, the Prince Consort noted the "acquisition of knowledge by ocular observation, comparison, and demonstration". To make this possible for their scholars was a primary object of the Commissioners. Knowledge must first be gained and scientific investigation advanced, but this alone did not extend the influence of science on productive industry. It was with this latter object, then, that their Industrial Bursary scheme was devised—directed, as stated in their Report for 1911, to encourage the training of 'captains of industry'. At that date the engineering faculties of the universities and the technical colleges established in many large towns were well organised. Students were leaving in numbers, who might with great advantage be utilised in factories and engineering works, but they were not welcomed. It was the object of the Commission to guide in the right direction this stream, broadened by the inflow of that practical experience without which the science of the schools was of little use to the engineer, the

electrician, or the shipbuilder. Such practical experience, they saw, could only be gained, in the future as in the past, by a period of apprenticeship, during which, in the opinion of most employers at that date, the apprentice was of little or no value and was paid accordingly. Since then conditions have changed to some extent, and far-seeing employers have come to recognise that it may be well worth while to pay an apprentice with a trained mind and a competent knowledge of science a living wage, because of the additional value he will possess in consequence of his previous college training, when he has acquired practical experience in the works or office.

However, in 1911, this was not the case, and the Commissioners—Lord Esher was their chairman, supported by Sir Arthur Rucker, and to their active help the scheme owes much—sent their secretary, Mr Evelyn Shaw, on a tour of the principal provincial universities and technical colleges to obtain information on which to base a plan for introducing more men with scientific training into industry. The secretary's conversations with the authorities of the institutions he visited led him to formulate the scheme of the Industrial Bursars which was afterwards adopted by the Commission. His scheme was a simple one, and from the first it worked. Each year a selected number of colleges and technical schools are invited to nominate students, desirous of entering industrial work, who have passed through their course with credit and are certified by their teachers to be suitable for such work, but are unable to meet the expense of an apprenticeship course without some financial help.

To these nominees some twenty or twenty-five bursaries are awarded. Each case is examined carefully: the Commissioners assure themselves that the man is competent—the school records and the statements of the teachers afford material for this, inquiry is also made as to his means, and not the least interesting part of the work has been the insight it has afforded into the efforts made by parents to secure for their children a college training and by the children to profit by it. An examination of the returns made to the secretary in some seventy pre-War cases taken consecutively from the Report gives these approximate averages: family income, under £175, number of children in family, 2.7, wage of bursar (per year), under £35.

The Record of the Industrial Bursars just issued gives the careers of about three hundred appointed.\*

\* The total number appointed has been 353, but a number obtained remunerative posts without assistance from the Commission, and for this reason their record is not included. The scheme was suspended during the War.

in the fifteen years up to 1929. The bursars are placed in selected works, chosen frequently by themselves, but subject to the approval of the Commissioners, who receive periodically reports as to the progress of their bursars. They are paid an amount which, with the wage received—in too many cases, only a small one—will bring the income of each man up to a sum on which he can live. The value of a bursary necessarily varies from man to man: in some cases the holder must spend from two to three years in learning the technique of his trade, for others a few months suffice, the average cost spread over the whole period works out at about £150 for each bursar.

The Record gives a list of the nominating institutions, with the number of bursars appointed from each, and continues with the names of the bursars and the period of their tenure. A statement follows as to the course of training and the subsequent career, so far as particulars are available. The compilation of these has involved no small amount of labour on the part of the secretary and his staff, who have well earned the thanks of the Commission—one may add, also, of the readers of their Record—for the interesting results of their work.

Of the bursars, some few have in the end devoted themselves to educational or scientific pursuits, while the War claimed a number among its victims; but the analyses at the end of the volume show that they are to be found holding responsible positions in the government services, the coal, iron and other allied industries, in every branch of engineering, as well as in the chemical, textile, and other leading trades. Of the three hundred whose careers are recorded, it will be found that, although the oldest among them cannot be much above forty years of age, at least forty have become directors or managers or reached some equally important positions. This fact in itself may fairly be cited as evidence that the scheme has rendered valuable service to industry, and while the need for a scientific training is now much more fully recognised than it was twenty years ago, and applications for suitable student-apprentices are made frequently to the universities employment bureaux, there is still need for the Industrial Bursary Scheme of the Royal Commission.

Much of the success of the scheme is due to the support given to it by employers, who have learned to appreciate the value of the trained men whom it supplies; it is no longer a pioneering effort but has gained the right to rank as one more of the successful endeavours made by the Commissioners to give effect to the "plan" devised by their founder.

## Obituary

THE RIGHT HON. SIR HORACE PLUNKETT,  
K.C.V.O., F.R.S.

ON March 26 died Sir Horace Plunkett, after a brief illness, though it was only the culminating attack of many years of ill health. He was born in 1854 of distinguished stock belonging to one of

the oldest families of the Pale, the third son of the sixteenth Lord Dunsany. Educated at Eton and University College, Oxford, considerations of health led him to America soon after taking his degree, and there he took up cattle-ranching in Wyoming. He was successful enough to be able to return to

Ireland ten years later with a fortune and a stock of experiences from which his gentle humour often drew an illuminating commentary on the subject under discussion. His business interests took him back to America almost every year, and the friendships he formed with leading men in the United States were often of service in enlightening public opinion both there and here.

From 1890 onwards Plunkett threw himself wholly into the movement for the regeneration of Irish life and particularly of its agriculture. From the outset the movement aimed at remaining outside party and uniting men of all classes and creeds in the single cause of economic and social progress. In 1894 he launched the Irish Agricultural Organisation Society, the pioneer and for many years the example of agricultural co-operation in the English-speaking world. On its Board sat parish priests and Presbyterian ministers, landlords and tenants, Orangemen and Jesuits, and as they worked together in amity under Plunkett's inspiration they set a standard of public service that was new in Irish affairs. Soon afterwards Plunkett got together the famous 'Recess Committee', again representative of every grade of Irish opinion, and its Report was a detailed consideration of what could be done by the State to promote the regeneration of the agricultural and industrial life of the country. It bore fruit in legislation which set up in 1899 the Department of Agriculture and Technical Instruction with an endowment independent of Treasury sanction and the annual vote, and of this new body Plunkett was made vice-president, in effect, acting minister. Plunkett chose his lieutenants well, unorthodox as were the appointments from an Irish party point of view. Mr T P Gill was made secretary and administrative chief, Prof J R Campbell was brought from Leeds to organise the agricultural side, and Mr George Fletcher was put in charge of the general education—a Scotsman and an Englishman who rapidly removed any reproach of alien origin. Campbell's practical outlook and sympathy with the Irish peasant found expression in a different policy from that adopted in England, where efforts were chiefly directed to higher agricultural education, but as time went on its wisdom was abundantly justified.

The appointment, however, of T P Gill, who had been prominent in Nationalist politics, raised an immediate storm, so contrary was it to the strict tradition of Irish party life. The extreme conservatives started a vendetta against Plunkett, his seat was contested and he was defeated in 1900, and though he stood later for a Galway division he never succeeded in re-entering Parliament. He was allowed to retain his vice-presidency until the advent of a Liberal Government in 1906, when he had to resign. For the Nationalists had declared against him, they would allow no other organisation in Ireland, and the party drew much of its funds from the country traders, who felt threatened by the co-operative movement. Plunkett then resumed his presidency of the Irish Agricultural Organisation Society, and became more active than ever in his efforts for the reconstruction of Irish

rural life. About this time came his chief books, "Ireland in the New Century", "The Rural Life Problem in the United States", "Noblesse Oblige", and "Plain Talks to Irish Farmers", a series of articles in the *Irish Homestead*, the paper he had founded as the organ of the co-operative movement and for which he had enlisted George Russell (*Æ*) as editor. Plunkett had no great interest in literature as such, but he took infinite pains over his writing and succeeded in giving eloquent expression to his convictions. Meantime the co-operative movement, guided by the I A O S, was making steady progress, and in 1913 was allowed to receive a grant from the Development Commissioners in the face of the declared opposition of the Nationalist party. The War cut across all these activities, and the passions then let loose destroyed the hopes of those who saw in that body, where Nationalists and Ulstermen, Catholics and Protestants, worked harmoniously for a common purpose, the spirit out of which a new Ireland would grow.

In 1917, Plunkett was chosen chairman of the Irish Convention, a representative conference of Irishmen to draw up proposals for the future Constitution of Ireland. Plunkett laboured unweariedly and nearly achieved a success that would have saved much of the terrible aftermath of war in Ireland, but the extremists prevailed and the Convention broke down. It was in these later troubles that his house near Dublin, built by Plunkett as a home in which he could gather all friends of Ireland, was destroyed, and henceforward he lived in England. In 1919 he endowed the Trust which bears his name, a foundation charged to keep before the public the principles of rural betterment, and on its behalf he was still working until a few days before his death. In recognition of his services to the scientific development of agriculture, Plunkett was elected to the Royal Society in 1902, and at the Dublin meeting of the British Association in 1908 he was the chairman of the newly formed Sub-Section of Agriculture. He had no working acquaintance with science, and in one sense his mission was to counteract the disintegrating effects of science upon the old fabric of rural society, but he was interested in the progress of science and knew that science among things must be controlled by science among men. He had no hostility to modernities, he became an early and passionate motorist, and was learning to fly only three years ago.

Such were the main items in the life of one who was indeed the most unselfish of all public men of his time. Of his personality it is difficult to write, by one who was honoured by his friendship. He was the true aristocrat, dedicated to the service of others, beyond all suspicion of self-seeking, free even from vanity. He made friends in all classes and treated them all on the same terms, but he always preserved his quiet dignity, the dignity of one in pursuit of a noble ideal. In this pursuit he never wavered or spared himself, though he suffered from a succession of illnesses which might have given any man an excuse for withdrawal from unnecessary fatigue. *Noblesse oblige*

A D H

## MR H CHAPMAN JONES

THE death of Henry Chapman Jones on March 7, at the age of seventy-seven years, removed one who has held an honourable place in the teaching of chemistry and in the development of the science and practice of photography. Apart from an early association with Birkbeck College, Chapman Jones's career as a teacher of chemistry was bound up with the Royal College of Science, where he was successively assistant, demonstrator, and lecturer, from 1881 until 1914, when he retired. In the first few years of this long period he was on Sir Edward Frankland's staff, and later he served under T E Thorpe, W A Tilden, and H B Baker. For a number of years he presided over the North Laboratory in the old Royal College of Science buildings, and many who worked there will recall the quiet, serious, and kindly way in which he went about his duties, as well as the high standard of industry and accuracy which he expected of his students.

The main contributions to knowledge made by Chapman Jones were in the domain of photography, and were published principally under the auspices of the Royal Photographic Society. Following Sir William Abney in the application of scientific method to the problems of photography, Chapman Jones dealt with such matters as the densities of negatives, the factors affecting the sensitiveness of plates, media of high refractive power for photomicrography, and the relationship between the size of the particle and the colour of the image.

Besides original papers on these and other topics, Chapman Jones contributed many articles on photographic subjects to the technical press, while two books on photography came from his pen, namely, "Science and Practice in Photography", which ran to four editions, and "Photography of To-day", a popular treatise published in 1913. His associations with the Royal Photographic Society were very close, and after being honorary secretary from 1892 until 1897, and vice-president from 1897 until 1902, he became president of the Society in 1912. In addition, he was a fellow of the Chemical and Physical Societies and of the Institute of Chemistry.

Chapman Jones was a single-minded man, whose integrity and ideals were of the highest. His quiet, almost shy, old-world courtesy and his modesty were marks of an interesting personality which only those who knew him well could appreciate. At the same time, he held strong opinions on many subjects, and he did not hesitate to express these in his own direct, unimpassioned way. His gentle, warm-hearted nature revealed itself to best advantage in the circle of his own family and of those who knew him intimately. He is survived by a widow and two sons.

J C P

## DR MICHAEL PERKINS

MICHAEL GERARD LAURENCE PERKINS died, following an attack of scarlet fever which developed apparently into a general septicæmia, on March 14, at thirty-three years of age. Perkins was educated at St Peter's College, Westminster, King's

College, London, and Trinity College, Cambridge. He was Huxley Prizeman at King's College and a Senior Scholar of Trinity. He was elected to the Mackinnon Research Studentship of the Royal Society in 1925. He took his M A in 1926, his Ph D in 1930, and joined the Westminster Hospital Medical School in 1927.

Michael Perkins had many interests, his greatest love being that of natural history. He had a keen intelligence, a vivid imagination, and boundless enthusiasm and energy—qualities which might have earned him a prominent place in the ranks of science. He published work on the Coleoptera of Guernsey and Wicken Fen, on Cambridgeshire Planarians, and, becoming interested in the Crustacea, published in 1928 a simple key to the crabs (*Brachyura*) of Britain and the north-eastern Atlantic. His own observations on local varieties of a species of *Platyhelminthe* worm, of which the peculiarities seemed to be correlated with slight changes in environment, led him to take an active interest in the work of the late Dr Kammerer. It was partly through the influence of Perkins that Kammerer was invited by the Cambridge Natural History Society (of which Perkins had been secretary for two years) to demonstrate his specimens and to discuss his much-disputed experiments. Perkins' interest in the problems of parasitism brought him into touch with the remarkable sex change induced in crabs by *Sacculina*, a phenomenon which he studied from the biochemical point of view in Cambridge (see *NATURE*, 124, 299, 1929). He was also engaged upon work on the respiratory metabolism of bats.

Perkins' work was perhaps marred by the diversity of his interests, his restless mind preventing that concentration necessary for the successful completion of a single piece of work. Time, however, was steadying him, and there is much that is valuable in the mass of unpublished data left by him.

Perkins' lovable nature was his chief characteristic, his ready optimism, his wit, and his profound knowledge of a multitude of subjects, ranging from folklore to mystery plays, won him innumerable friends and made him a most agreeable and interesting companion. His boundless energy and zeal were ever at the service of others. His early death has come as a great shock to all who knew him and loved him so well. There are many who will sympathise with his bereaved parents in their great loss.

J H Q

WE regret to announce the following deaths

M Guillaume Bigourdan, president in 1924 of the Paris Academy of Sciences and formerly director of the Bureau International de l'Heure, on Feb. 28, aged eighty years.

Dr R M Bronte, pathologist to the Home Office and formerly Crown Analyst in Ireland, on March 22, aged fifty-two years.

Prof Wilhelm Ostwald, emeritus professor of chemistry in the University of Leipzig, Nobel prizeman in chemistry for 1909, and an honorary fellow of the Chemical Society, on April 4, aged seventy-eight years.

## News and Views

## Sir William Pope

By awarding the Messel medal to Sir William Pope, the Society of Chemical Industry has paid a well-deserved tribute to one of Great Britain's most distinguished chemists. Moreover, the news of the award will be received with interest and satisfaction outside as well as within the boundaries of his own country, for Sir William, as president of the Federal Council and a former president of the Union Internationale, is well known to foreign chemists as the principal ambassador of their British colleagues. He held office from 1917 until 1919 as president of the Chemical Society, and from 1920 until 1921 as president of the Society of Chemical Industry. Sir William Pope, who was born in London in 1870, was one of Prof. H. E. Armstrong's pupils, having studied chemistry at the Finsbury Technical College and at the Central Technical College (now an integral part of the Imperial College of Science and Technology) at South Kensington. In 1897 he became head of the chemical department at the Goldsmiths' Institute, New Cross, and in 1901 became professor of chemistry at the Municipal School of Technology, Manchester, in 1908 he was appointed professor of chemistry and director of the Chemical Laboratories at Cambridge. Sir William's greatest triumphs in the domain of original research are associated with advances in stereochemistry, but other studies, for example, those with Dr. W. H. Mills on photographic sensitizers, are equally important and well known. Working in collaboration with Peachey, he succeeded in 1889 in resolving phenylbenzylmethylallylammonium iodide, an optically active compound containing an asymmetric nitrogen atom, and so demonstrated the quinquivalence of nitrogen. This extension of the scope of stereochemistry beyond the range of asymmetric carbon compounds was followed by the preparation of optically active substances containing asymmetric atoms of sulphur, selenium, and tin. In association with Barlow, he published work on the relation between chemical composition and crystalline form which led to interesting conceptions concerning the size and arrangement of atoms.

## Mellon Institute of Industrial Research

MR. ANDREW MELLON, the newly appointed American Ambassador in London, has a claim to fame in relation to the promotion of scientific research which has escaped recognition in announcements of his appointment. He and his brother, Richard B. Mellon, gave their name and a generous benefaction to the Mellon Institute of Industrial Research in the University of Pittsburgh. Of the original benefaction of £100,000, half was used to provide the permanent building accommodating 70 research workers, £12,000 for equipment and apparatus, £4000 for the chemical library, and £8000 a year for at least five years for maintenance. The objects of the Institute are stated to be "The increase of useful knowledge through the application of contemporary science to industrial processes, the promotion of American industry, and

providing opportunities for the training of men for high industrial appointments, and, in addition to this, the training of men in advanced chemical engineering and industrial chemistry for specific industries." The principles on which the work of the Institute was based were enunciated by the first director, Prof. Robert Kennedy Duncan, and were explained for English readers in Educational Pamphlet No. 30, entitled "An Experiment in Industrial Research", by T. Ll. Humberstone, published by the Board of Education in 1915. It is a tribute to the wisdom of the founders of the Mellon Institute, and the essential soundness of the principles on which the Institute is based, that the Liberal party in an official statement of policy recently published has urged the establishment in Great Britain of an institute on similar lines.

## Industrial Bursaries

It is now almost platitudinous to say that industrial efficiency can be furthered by the introduction into works and factories of men trained in science and ready to use such training in industrial pursuits. The difficulty, however, is to find really suitable openings for students whose special scientific training will ultimately fit them for responsible posts. It is true, of course, that employers are realising more and more the value of such men to industry, but it is not always easy for students to gain practical experience when their financial position is such that they cannot accept employment at the nominal remuneration which usually accompanies the 'learning period' in industry. In these cases the Industrial Bursaries of the Royal Commission of 1851 are specially useful. The scheme is designed to assist "young men who, after a course of training in a University or approved technical college, desire to take up Engineering, Chemical or other industrial work." It has no intention of facilitating collegiate studies, it is solely "to enable suitable applicants to tide over the period between their leaving college and obtaining remunerative employment in industry." To carry out its full intention, the candidate must be under twenty-five years of age, must have been a *bona fide* student of science for three years, must be able to obtain an industrial post approved by the Commissioners, and must be in need of pecuniary assistance to enable him to hold such a post. He is not allowed, except in particular circumstances, to accept less than the standard wage. Elsewhere we publish an article dealing with the record of bursars appointed between 1911 and 1929, and we shall not, therefore, deal with the actual record here. In spite of that part of the regulation which we have indicated above, however, it would appear that the bursars were nominated chiefly by universities only the Heriot Watt College, Edinburgh, would fall under the heading of "approved technical college." We would, therefore, direct the attention of technical colleges to the scheme, for we feel that it would be of enormous value to students who may not contemplate proceeding to universities.

but whose whole training fits them admirably to fulfil just that purpose which the Commissioners have in mind

#### Volcanic Eruptions in the Andes

ALARMING reports of vast showers of volcanic ash from eruptions of Descabezado and other recent volcanoes of the group which occurs on the chain of the Andes south of Santiago de Chile, appeared in Tuesday's daily papers. The eruptions began on April 10, and the neighbouring towns of San Fernando, Curico, and Talca were said to be in darkness through the fall of fine dust from the volcanoes. The ash is reported to be three feet deep in Curico. Trains arriving at Mendoza, on the line about a hundred miles east of Santiago, were covered with volcanic dust, and the streets of the city were thickly coated with it. At Buenos Ayres, which is about six hundred miles farther east, there has been a steady fall of volcanic ash, and even at Monte Video (Uruguay), still farther east, the shower of dust is reported to have lasted for ten hours. Shocks have been felt over a wide area, but at the time of going to press no details are available as to the actual character of the eruptions or exactly what volcanic peaks have again come into activity.

#### Overlapping of Government Research Funds

It has been common knowledge, amongst those conversant with such matters, that a certain amount of overlapping has existed in connexion with the grants made by Government to various bodies who utilise the money for assisting research and other work in the British Empire. The system underlying these grants has developed by instalments and does not, therefore, represent a carefully thought-out scheme. For this reason the first report of the Estimates Committee, of which Sir Vivian Henderson is chairman, recently presented to the House of Commons, will be welcomed. It is understood that the Committee has examined the estimates of the following funds: Empire Marketing Board, Colonial Development Fund, Development Fund, Ministry of Agriculture, Colonial and Middle Eastern Services, and University Grants Committee. The Estimates Committee's object was to ascertain to what extent in recent years Parliament has been asked for funds to assist the same object or body through different channels, since the Parliamentary estimates do not themselves indicate clearly the sources of the demand. The Committee has noted, for example, that grants are being allotted to the Empire Marketing Board for many purposes which are also assisted by the Development Fund, the Forestry Commission, the Ministry of Agriculture, or the Department of Scientific and Industrial Research. Again, in the case of the Colonies, grants are being made from the Colonial Development Fund for the ordinary purposes of Government, whilst at the same time, the Colony concerned may be receiving a grant from the Colonial Office. It is not suggested that the departments or bodies receiving such grants are in ignorance of what is being done by others working on the same lines, but the fact remains, as the Committee

remarks, that many institutions in Great Britain are receiving assistance from the State through two or three, or even as many as four or five, or more, channels. This position of itself justifies the appointment of the Estimates Committee, the work of which should also prove of service to Government at the Ottawa Conference.

#### Race Prejudice and World Peace

SIR ARTHUR KEITH in his address, "Can Race Progress be Rationalised?", delivered on April 5 at Oxford, before the Universities Congress of the National Union of Students, turned once more to the problem of world peace as it presents itself to him as an anthropologist and a follower of Darwin. As he has expressed himself on more than one previous occasion, Sir Arthur is convinced that racial and national instinct is an all-powerful factor in the evolutionary progress of mankind, producing new and, perhaps, better races; but, as he points out, this spirit is incompatible with man's economic needs, and the result is the disharmony which is to be seen in the world to-day. Granting that this spirit is ineradicable, and accepting the inevitable consequence that the nations of the world can never be welded into a whole, is it then possible, Sir Arthur asks, to bring about conditions in which each nationality may work out its destiny by peaceful progress? Ethically the nations of to-day are in no respect superior to their predecessors, each pursues its own ends selfishly. Nothing daunted, Sir Arthur sees hope for the future in such manifestations as the suppression of separatist tendencies by reason in Scotland and Wales, and in the spread of English-speaking peoples, which he regards as the greatest attempt to rationalise the peoples of the world that has ever been made. Race progress, he concludes, can be rationalised only by a process of self-understanding, self-education, and, if need be, self-sacrifice on the part of all.

#### Roman Mining in Britain

In a paper on Roman mining in Britain, read before the Newcomen Society on March 30, Mr. G. C. Whittick gave a review of the mining operations during the whole of the Roman occupation. Though the Roman invasion cannot be ascribed chiefly to the desire to gain possession of the country's mineral wealth, after the initial seizure of the south-east of the island, there followed the inevitable accompaniment of the exploitation of minerals, particularly lead. After referring to the mining methods, to the treatment of ores, and to the question of organisation, Mr. Whittick dealt with the mining of coal, gold, copper, lead, iron, and tin. During the first century and a half of the Roman occupation, lead was the most important product of Britain. Lead mining in the Mendips was apparently begun so early as A.D. 49, and production rose rapidly during the reigns of Nero (A.D. 54-68) and Vespasian (A.D. 69-79). The centre of Roman activity in the district was in the valley of the Blackmoor, just south of Blackdown. The ore was obtained from surface workings, and from the waste heaps of the workings many pigs of Roman lead have been recovered. Lead was also

mined in Flintshire, Derbyshire, Yorkshire, and Shropshire. Most of the pigs which have been found bear inscriptions, and some have been officially stamped showing that they had been desilverised. The iron-workings of the Roman period were concentrated in the Weald and in the Forest of Dean, and tin mining was carried out to a small extent in Cornwall.

#### Velocity of Light

MR M E J GHEURY DE BRAY, 40 Westmount Road, Eltham Park, London, S E 9, has published, in the form of a pamphlet entitled "La vitesse de la lumière", a critical and documented discussion of the chief experiments made to determine this constant, from the pioneer work of Romer and of Bradley, down to the latest experiment devised by Michelson. The experiments are carefully analysed, and the accounts contain discussions of certain errors, obscurities, and irrelevancies which disfigure the presentation of the subject in many of the texts. The description of the observations of Romer and of Bradley is specially useful. The author presents a table which shows the results of some twenty-one experiments, beginning with that of Fizeau in 1849 and concluding with the recent work of Michelson. Of these experiments he decides, after critical consideration, that seven give trustworthy results. He divides these into two groups—experiments carried out on a short base line and those carried out on a long base line. The results are summarised as follows:

##### (1) Bases courtes, inférieures à 4 Km

|        |           |         |
|--------|-----------|---------|
| 1879 5 | Michelson | 299 910 |
| 1882 7 | Newcomb   | 299 860 |
| 1882 8 | Michelson | 299 853 |

##### (2) Bases longues, 23 Km et plus

|        |               |         |
|--------|---------------|---------|
| 1874 8 | Cornu-Helmert | 299 990 |
| 1902 4 | Perrotin      | 299 901 |
| 1924 6 | Michelson     | 299 802 |
| 1926 0 | Michelson     | 299 796 |

The conclusion reached is that "un fait très remarquable est tout de suite révélé par cette classification dans les deux groupes, la vitesse de la lumière diminue progressivement avec le temps, et le changement de vitesse est approximativement proportionnel à l'intervalle de temps correspondant." However this may be, there is no question that Mr Gheury de Bray has provided a useful résumé of the literature dealing with a very difficult experimental problem.

#### Ocean Newspapers

SINCE the first issue of the *Transatlantic Times*, which appeared in the form of a leaflet on the *ss St Paul* on Nov 15, 1899, maritime journalism has made great progress. All newspapers issued on British ships are now published by an organisation known as the Wireless Press. In the first place, it supplies ships with copies of the journals prepared in such a way that the news can be printed on board ship as it is received by the ship's radio operator. Rugby Radio, the G P O wireless station, daily transmits three news bulletins—in the early morning, at midday,

and during the evening. It also transmits a Saturday night message giving the League football results. This message is in keen demand among the crews on cargo boats all over the world. In the case of general elections, big races, and other events of world-wide interest, it often happens that a passenger in mid-Atlantic is reading the results before they have been distributed on land. The special bulletins, broadcast throughout the day, are exhibited prominently for the passengers to read. Foreign stations also bombard the ship with news. The ship's purser has the task of sub-editing the newspaper. In an interesting paper on maritime journalism, by E C Thomson, in the *Wireless World* for March 23, it is stated that there are indications that the 'wireless news' will give place, possibly at no distant date, to a replica of a journal printed on land. This could be achieved without much difficulty by means of facsimile telegraphy. A complete page printed on land could be reproduced on board ship in a shorter time than would be required to carry the actual newspaper from one end of Fleet Street to the other.

#### Archæological Exploration in Macedonia

THE recently issued *Annual of the British School at Athens*, No 30, covers the sessions 1928–29 and 1929–1930 (London: Macmillan and Co., Ltd., £3, 3s). In addition to the annual report and financial statement, it includes the usual complement of papers by members of the School. The excavations in Macedonia have been continued, and although the account of the work carried out by Mr W. A. Heurtley and others at Saratse provides no sensational discovery, it demonstrates the relation of cultural development in an interesting strip of country to that of the Vardar valley and the area immediately around Salonika. A Troadic site at Thermi in Lesbos was excavated by Miss W. Lamb, who describes the five successive cities of an Anatolian colony which was finally abandoned some time before the sack of Troy II. The excavations are still incomplete after two seasons' work. Messrs J. D. and H. W. Pendlebury describe two extensive and elaborate protopalatial houses at Knossos, found at the bottom of walled pits in the west court. It is unfortunate that owing to their position they cannot be excavated, but a somewhat hazardous feat of exploration has revealed their character to a considerable extent. The first instalment of a study of the morning hymns of the Emperor Leo by Prof. H. J. W. Tillyard provides evidence on medieval methods of musical notation of considerable interest to students of early music. Mr J. D. Beazley's "A Dancing Maenad" is a study of the grouping and meaning of figures on a Nolan amphora from Woburn Abbey. Nearly half the volume is devoted to the continuation of the final report on the School's important excavations at Sparta in 1924–28 by the former director, Mr A. M. Woodward.

#### Animals Playing at being Hunted

A HAND-REARED female of the prongbuck, or American antelope, owned by Mr L. T. Murray at Mertzon in Texas, displayed a most remarkable

originality in getting itself hunted, as related by its owner in the *Journal of Mammalogy* for February, p 41 Its habit, as it was allowed complete liberty, was to go to the main street of the little town and entice dogs to pursue it, the resulting hunt might last as long as three-quarters of an hour, at the discretion of the doe, which had so much the advantage of her pursuers in speed and intelligence that she did as she liked with them, fleeing in pretended fear, circling and waiting for them to come up, and then darting off in the opposite direction, until at last she left the pack behind and went home It is satisfactory to learn that she came to no harm and was ultimately sent to a park and bore twins, but it would be interesting to know if playing at being hunted is a recreation indulged in by animals we usually regard as food for others, when they live in the natural state That the hunters may play at hunting we know from what has been observed of the puma and the peregrine falcon

#### Excavations in Texas Caves

THE Smithsonian Institution, it is announced through Science Service, of Washington, D C, is sending an expedition to the caves of western Texas in charge of Mr Frank M Setzler, staff archaeologist The object of the expedition is to obtain evidence of the culture of the early cave dwellers of this area, and if possible to ascertain their relation to the basket makers who preceded the Pueblo-Indians of the south-western states Traces of the basket-makers' culture have already been found in Texas caves, but there is also evidence, in spear points of stone associated with the bones of extinct animals at some depth below the earliest basket-maker relics, of an earlier people

#### Modern Aids to Teaching

A QUARTERLY review of modern aids to teaching, entitled *Sight and Sound*, has been published under the auspices of the British Institute of Adult Education The first issue contains thirty pages, and is illustrated It is edited by a committee appointed by the Institute, and its purpose is to promote interest in the use of modern scientific inventions, such as the film, gramophone, wireless, and television, in schools and colleges and in general cultural work The gramophone and wireless have already shown their usefulness in the teaching of languages and music, one of the articles in the issue maintains that the teaching film should be planned, made, and used in the school

#### New Physical Apparatus

In their new catalogue, No 115X, of forty pages, Messrs Griffin and Tatlock, Ltd, give an account of some new models of physical apparatus designed for use in the teaching of physics Under the name Microid Physical Series some twenty new designs have been produced, based for the most part on modern research methods Each apparatus is described in a 'specification', and this is followed by 'experimental notes' which will be useful to the teacher and the student, especially as in many cases numerical results from an actual experiment are

quoted As indicating the type of apparatus included, mention may be made of the microcel thermopile, the thermo-magnet illustrating the heavy currents obtainable from thermo-elements under suitable conditions, the magnetic potentiometer (Chattock), and the moment of inertia apparatus with rotating table Experiments are also included on light, such as the parallel plate refractometer, and heat, such as the micrometer expansion apparatus, to mention only a few of the methods described References are given to the textbooks of Pohl, Searle, and Worsnop and Flint Teachers of physics will find here many suggestive hints for experimental work

#### Announcements

DR DUKINFELD H SCOTT, F R S, the eminent palaeobotanist, has been elected a corresponding member of the Prussian Academy of Sciences

THE Faraday Medal of the Institution of Electrical Engineers will be presented to Sir Oliver Lodge at the ordinary meeting of the Institution to be held on April 21 at 6 p m The presentation will precede the twenty-third Kelvin Lecture, which will be delivered by Dr W E Sumpner, on "The Work of Oliver Heaviside"

UNDER the auspices of the British Science Guild, Prof S Chapman, professor of mathematics at the Imperial College of Science and Technology, will deliver a popular lecture on "Polar Lights", on Wednesday, May 25, at 5 p m The lecture will be at the Royal Society of Arts, John Street, Adelphi, W C 2 Tickets, for which no charge is made, can be obtained on application to the Secretary, British Science Guild, 6 John Street, Adelphi, W C 2

THE Dyers' Company Gold Research Medal for the period 1930-31 has been awarded to Prof F M Rowe, professor of colour chemistry and dyeing in the University of Leeds, for a series of three papers on the chemical and physical effects of kier boiling on insoluble azo colours on the fibre This is the third occasion on which Prof Rowe has received this medal, the earlier awards being made for the periods 1924-25 and 1926-27 for his investigations of other aspects of the chemistry of azo colouring matters

PROF W L BRAGG, F R S, professor of physics, Victoria University of Manchester, the Rev Canon H Maynard Smith, Canon Residentiary of Gloucester, and the Right Hon J. H. Whitley, chairman of the British Broadcasting Corporation, formerly Speaker of the House of Commons, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

THE following appointments to the Colonial Agricultural Service have recently been made by the Secretary of State Mr W E Bassett, formerly assistant superintendent, Victoria Botanic Gardens, Nigeria, to be assistant agricultural officer, Dominica, Mr T R Hayes, superintendent of agriculture, Gambia, to be agricultural officer, Uganda, Mr F L Squibbs, assistant agricultural officer, Leeward

Islands, to be assistant director of agriculture, Seychelles, and Mr I G C Squire, assistant manager, Oil Palm Plantations, Sierra Leone, to be manager, Government Plantations, Zanzibar

THE American Association for the Advancement of Science will hold its second summer meeting at Syracuse, New York, on June 20-25. The third summer meeting will be held at Chicago in connexion with the Century of Progress World's Fair on June 19-30, 1933. The centre of this meeting at the World's Fair will be the Hall of Science, in which nearly ten acres of floor space will be devoted to science exhibits. Seventy-five European men of science will be invited to attend this meeting as guests of the American Association.

THE twenty-second annual May lecture of the Institute of Metals will be delivered by Dr F Korber, director of the Kaiser-Wilhelm-Institut für Eisenforschung, Dusseldorf, on Wednesday, May 11, at 8 P.M., at the Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W.1, the subject of the lecture being "The Plastic Deformation of Metals". Cards of invitation may be obtained from Mr G Shaw Scott, 36 Victoria Street, S.W.1.

THE amalgamation of the Optical Society and the Physical Society of London has been under consideration for some time. It has now been decided to proceed with the amalgamation. Certain alterations are to be made in the articles of association of the Physical Society, and, in due course, a general meeting of the Optical Society will be held to wind up the Society.

FARMERS' and farm workers' associations and clubs, chambers of agriculture and horticulture, students' societies, and other bodies interested in agriculture or market gardening are invited to inspect the Rothamsted and Woburn Experimental Plots during the coming summer. Mr H V Garner and Capt E H Gregory will be available to demonstrate the plots. All communications and requests to visit the Stations should be addressed to the Secretary, Rothamsted Experimental Station, Harpenden.

THE autumn meeting of the Iron and Steel Institute will be held in London on Sept. 13-15, concurrently with that of the Institute of Metals. It has been provisionally decided that at least one joint session shall be held at which papers of interest to the members of both Institutes shall be presented and discussed. Other sessions will be held separately but concurrently.

At the recent annual meeting of the Institution of Automobile Engineers, Major C G Nevatt was elected president of the Institution for the session 1932-33. The summer visit of the members of the Institution will this year take the form of a four days' trip up the Thames to Oxford on June 8-11, including visits to Morris Motors, Ltd., and the Pressed Steel Works of Great Britain.

ANOTHER of the valuable catalogues (No. 456) of Messrs Bernard Quaritch, Ltd., 11 Grafton Street, W.1, has reached us. It deals with nearly 1500 works on zoology, geology, and palæontology, and should be

of interest to students of these branches of science and to librarians.

MESSRS Bowes and Bowes, 1 Trinity Street, Cambridge, have just published a catalogue (No. 461) entitled "Old-time Literature (a third Catalogue), principally of XVIIth and XVIIIth centuries", containing particulars of nearly 1700 second-hand books on a variety of subjects, several of which relate to scientific matters.

THE following books are announced for early publication by Messrs Longmans and Co., Ltd.: "The Causes of Evolution", Prof. J B S Haldane, "A Manual of the Flowering Plants and Ferns of the Transvaal, with Swaziland, South Africa", Dr J Burt Davy—Part 2, "Malvaceæ to Umbelliferae" (completing the Archichlamydeæ), "Modern Methods in Quantitative Chemical Analysis", Drs A D Mitchell and A M Ward, "Modern Practice in Mining", Sir Richard Redmayne—Vol. 5, "Colliery Machinery and its Application", "Steam Engine Theory and Practice", Prof W Ripper, new and revised edition, edited by Prof W J Goudie, "Elements of Steam Power Engineering", Dr O Sneed, and "Graphical Geometry", E N Digweed.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—Male laboratory assistants, Grade II, at the Royal Arsenal—The War Department Chemist, B 47, Royal Arsenal, Woolwich, S.E.18 (April 23). A veterinary assistant at the Veterinary Laboratory of the Ministry of Agriculture and Fisheries, New Haw, Weybridge—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (April 25). An assistant master at the Mining and Technical Institute and Junior Technical Day School, Neath, with a degree in engineering and works experience in engineering—The Director of Education, County Hall, Cardiff (April 25). A woman demonstrator in inorganic and physical chemistry at the Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N.W.1 (April 30). A lecturer in botany at the Wigan and District Mining and Technical College—The Principal, Wigan and District Mining and Technical College, Wigan (May 2). An intelligence officer in the Engineering and Metals Section of the Department of Overseas Trade—The Chief Establishment Officer, Department of Overseas Trade, 35 Old Queen Street, Westminster, S.W.1 (May 5). Assistant civil engineers in the Civil Engineer-in-Chief's Department, Admiralty, and H.M. naval establishments at home and abroad—The Civil Engineer-in-Chief, Admiralty, S.W.1 (May 14). An assistant master at the Leyton Technical College, with a degree in engineering or its equivalent and experience in teaching—R J Geldart, 280 High Road, Leyton, E.10. An assistant chemist under the Research Association of British Paint, Colour, and Varnish Manufacturers—The Paint Research Station, Teddington, Middlesex. A laboratory steward in the Department of Physics of St. Thomas's Hospital Medical School—Dr J H Brinkworth, Physics Department, Medical School, St. Thomas's Hospital, S.E.1.

## Hexuronic Acid as the Antiscorbutic Factor

EXPERIMENTS are being carried out in order to decide whether 'hexuronic acid' is the antiscorbutic factor. So far as is known, the distribution of this acid in plants follows closely the distribution of vitamin C. In the animal body it can also be found in relatively high concentration in the suprarenal cortex. Its chemical properties closely agree with the known properties of the vitamin. It was discovered and isolated several years ago at the Biochemical Laboratory, Cambridge.<sup>1</sup>

The hexuronic acid used in the present series was prepared in crystalline form from beef suprarenal glands two years ago at the Chemical Department of the Mayo Clinic.<sup>2</sup> As is known, 1.5 c.c. of lemon juice is the minimum protective dose for guinea-pigs against scurvy. This quantity of lemon juice contains approximately 0.5 mgm of hexuronic acid. 1 mgm of the acid has been given to our test animals daily, since, owing to the long exposure to air, some of our hexuronic acid preparation may have been decomposed.

The general procedure used in studying the antiscorbutic activity of hexuronic acid was that recommended by Sherman and co-workers.<sup>3</sup>

The test period in the first experiment consisted of 56 days. At the end of that time the guinea-pigs which had been receiving hexuronic acid, as well as the positive controls which received 1 c.c. of lemon juice, were chloroformed. The positive controls showed mild scurvy on autopsy, while the animals receiving hexuronic acid showed no symptoms of scurvy at all. The negative controls, which received the basal diet only, had an average survival of 26 days and had typical symptoms of scurvy. In this experiment, however, only a small number of animals were used, and the animals receiving hexuronic acid, as well as the positive controls, were losing weight continually because the basal diet employed at that time contained no milk powder (it consisted of rolled oats, bran, butter fat, and salt). For this reason we decided to repeat the experiment.

In the test which is in progress at the present time the defects mentioned above have been remedied. A large number of animals has been used, and skimmed milk powder has been added to the basal diet.

The test was composed of the following groups: (1) Negative controls receiving the basal diet only, 9 animals. (2) Positive controls, receiving 1 c.c. of lemon juice daily, 8 animals. (3) Test animals receiving the basal diet and 1 mgm of hexuronic acid daily, 10 animals. (4) Controls receiving mixed diet, 10 animals.

The negative controls all died between the time limit of 20-34 days, with an average survival of 26 days, after a continuous and big drop of weight. They all had symptoms of severe scurvy.

At the end of 55 days all the animals receiving hexuronic acid, as well as the positive controls with lemon juice or mixed diet, were living apparently in good health and were gaining weight consistently. At this time three animals which received hexuronic acid and two animals which received lemon juice were chloroformed. Mild symptoms of scurvy were present

in the positive controls with lemon juice, but no signs of scurvy in the animals receiving hexuronic acid.

The test will be continued until the ninety-day period is over, and full details will be published later.

This research was supported by the Ella Sachs Plotz Foundation.

<sup>3</sup> Sherman, H. C., La Mer, H. K., Campbell, H. L., *J. Am. Chem. Soc.*, 44, 165, 1922.

At the wish and by the courtesy of Prof. A. Szent-Gyorgyi, I arranged to examine in my laboratory the 'hexuronic acid' which he isolated while working in the Biochemical Laboratory, Cambridge. At the end of 1929 he sent me 10 grams of the substance, which had been prepared in the chemical laboratory of the Mayo Clinic, Rochester, U.S.A. Owing to the value and scarcity of this material, it has been necessary to carry out each experiment with very small quantities, and to establish with much deliberation and care the experimental conditions and controls. This work is still in progress and is being directed to the elucidation of the constitution and the achievement of the synthesis of the substance, this has involved the study of its chemical properties, and the formation of a crystalline derivative. The preliminary results now communicated show that the hexuronic acid is most probably the 6-carboxylic acid of a keto-hexose, which does not appear to be related either to *D*-fructose or to the ketose corresponding to *D*-galactose. This work has been conducted by my colleague Dr. E. L. Hirst, assisted by Mr. R. J. W. Reynolds, whose report is given in the accompanying note.

W. N. HAWORTH

University of Birmingham,  
March 28

THE 'hexuronic acid' prepared from suprarenal glands by Prof. Szent-Gyorgyi was a cream-coloured micro-crystalline powder, m.p. 184°-187° (decomp.). On recrystallisation from methyl alcohol-ether the substance was obtained in irregular aggregates of rectangular crystals, which were almost colourless. No change in m.p., analysis, or other properties was observed even after several successive crystallisations. The crystals showed brilliant colours when observed between crossed nicols in a polarising microscope. Before and after recrystallisation the same analytical figures were obtained (Found: C, 41.0, H, 4.7.  $C_6H_8O_6$  requires C, 40.9, H, 4.5 per cent). Neither nitrogen nor methoxyl was present. In aqueous solution the rotation  $[\alpha]_D^{20} +23^\circ$  (c 1.1) increased slowly to  $+31^\circ$  (3 days) and then decreased to zero (11 days).

The hexuronic acid reduced Fehling's solution, neutral silver nitrate, and neutral potassium permanganate in the cold. It gave the Mohr's test and the orcinol reaction, but failed to show the naphthoresorcin colour test characteristic of glycuronic acid.

The hexuronic acid was monobasic (40 mgm of sodium hydroxide neutralised 172 mgm of substance—calc. for  $C_6H_8O_6$ , 176).

Oxidation by atmospheric oxygen in slightly alkaline solution, with a trace of copper as catalyst, introduced one carboxyl group in place of a primary alcohol

group and the product reduced Fehling's solution. Oxidation to the same stage occurred with remarkable rapidity when the hexuronic acid reacted with neutral, acid, or slightly alkaline potassium permanganate. The reaction, which required two atoms of oxygen per molecule of the substance, was thereafter much less rapid but proceeded regularly in the cold until one further atom of oxygen per molecule had been absorbed. The product was now non-reducing.

When heated with phenylhydrazine in dilute acetic acid, the hexuronic acid gave intractable, dark-coloured, amorphous products which could not be purified. The action of *p*-bromophenylhydrazine in dilute acetic acid on the barium salt of the hexuronic acid (compare Goldschmidt and Zerner, *Monatsh*, 33, 1217, 1912) gave a dark red micro-crystalline powder which, after recrystallisation from alcohol, had *m* p 230°-235° (decomp). Analysis showed it to be the *p*-bromophenylosazone of a hexose-uronic acid (Found C, 40.8, H, 3.5, N, 11.1, Br, 30.3.  $C_{18}H_{18}O_5N_4Br_2$  required C, 40.7, H, 3.4, N, 10.6, Br, 30.2 per cent). Control experiments with glycuronic acid and galacturonic acid failed to give the above substance. With glycuronic acid Goldschmidt and Zerner's barium salt of the *p*-bromophenylosazone of glycuronic acid was obtained, whilst the galacturonic acid gave a yellow powder which appeared to be mainly the barium salt of the corresponding galacturonic acid derivative.

The above reactions, together with Prof Szent-Gyorgyi's observation that oxidation by iodine in the cold removes two atoms of hydrogen, which are easily replaced by mild reducing agents, can be understood most readily on the following basis

Inasmuch as the configuration and ring-structure of the lactone of the hexuronic acid have not yet been established, the structural formulæ are given above in the open chain form, although the sugar-ring is most probably that of a keto-furanose.

### Biological Estimation of the Quality of Sewage Effluents

It is known that certain motile Protozoa and Bacteria gather near the surface film in water containing organic matter.

Fig 1 — *Polytoma uvella*, Ehr × 550, in Dobell's Iodine

*Polytoma uvella*, Ehr (Fig 1), one of the Phytoflagellata, in narrow upright tubes rests in a stable zone about 4 mm below the meniscus, and this reaction may be utilised in detecting organic impurities in water and estimating the biochemical oxygen demand of sewage and sewage effluents.

This organism abounds in the final settlement tanks at the Leeds Sewage Works. Cultures are obtained by aerating the humus from these tanks, *Polytoma* increasing in the supernatant fluid as the humus clarifies. Sub-culture is done in tubes of one-inch diameter. Equal parts of humus and bacteria

bed effluent are placed in these and partially sterilised in a water bath for an hour at 80° C. Boiling destroys the colloidal nature of the medium. The tubes are then inoculated from the previous culture, are kept at room temperature, and are not closed.

The working of the test depends partly on capillarity and is carried out in tubes of 4 mm bore. These are graduated 5 mm from the bottom and 40 mm above

Fig 2 — Climbing of *Polytoma* 'blanket' in tap water, mean of four tubes, continuous line, and in deoxygenated tap water, one tube, broken line. Tests start simultaneously. Temp range 49°-55° F. Deviation from mean is shown where scale permits.

this mark. The supernatant fluid of a culture is placed in the tube to the lower mark by means of a fine pipette provided with a long glass bead near the orifice to protect against fouling the sides. The water to be tested is run gently on to this to the upper mark

by an ordinary fine pipette. Inoculum and water lie distinct, and the exact distance to the meniscus is measured. The *Polytoma* gather at the junction in a formation which is called a 'blanket' on account of its characteristic appearance. This blanket mounts the tube at a speed which bears a close relationship to the purity of the water. The order of the movement is illustrated in the charts. In Fig 1 the rate of rise in ordinary and deoxygenated tap water is contrasted. In Fig 2 the manner in which the *Polytoma* detects slight contamination of the water is shown.

When the oxygen in solution is below one part in 100,000 parts of water, the blanket is sensitive to very slight differences, the less oxygen present, the more rapid the rise. When an excess of oxygen is present, the blanket is by so much depressed into the depths of the inoculum. Light and darkness and variations in the pH of the water are of no account, and the reaction proceeds steadily at all ordinary room temperatures. The presence of nitrates and nitrites in the water in amounts such as occur in sewage effluents retards the rate of rising.

In crude sewage or other highly polluted waters, the blanket disperses and regathers at the meniscus in less than an hour. Heavy roping is usual from this position in bad water. In tap water, the upward progress is steady, and in a few days the blanket reaches its stable zone well below the meniscus, and there remains. Between these wide differences in behaviour, all intermediate conditions have been observed. It is thus possible to refer waters to a series of grades in contrast to tap water, controls of which are included in every series. Five grades can be defined at present from readings made at the end of one hour and of four hours respectively. Subdivisions of the worst grade are rendered possible by suitable dilution of the fluid tested with tap water.

*Spirillum* is present in the cultures and possibly plays some part in the reaction. In young cultures, it accompanies the *Polytoma* in its climb, and may form

a conspicuous layer in the blanket. Cultures from 3 to 8 days old react best when *Spirillum* is not too abundant. With older ones, the *Polytoma* becomes sluggish, and its rise may be delayed for a day, except in foul waters. In a reaction thus delayed, *Spirillum* may leave the inoculum first, and the *Polytoma*

FIG 3—Climbing of *Polytoma* 'blanket' in tap water, one tube, continuous line, and tap water contaminated with stale urine at start of test, 1 per cent urine, dotted line, 0.5 per cent urine, broken line, mean from two tubes of each, deviations from mean are shown where scale permits. Temp range, 49°-57° F, 63° on second day for 2 hours.

blanket follow later and absorb its aggregation. Confusion may thus arise.

Through the courtesy of Mr J T Thompson, manager of the Leeds Sewage Works, I have been able to begin the study of this reaction under practical conditions. I have had the benefit of his expert knowledge of the processes of sewage purification, and access to the record of the analyses of the sewage and effluents tested, as done by Mr H Watson. The reaction has been demonstrated to the Royal Society of Tropical Medicine and Hygiene.

University, Leeds

#### The Variation of Penetrating Radiation with Zenith Distance

FROM the few investigations<sup>1</sup> so far made of the angular distribution from the zenith of penetrating radiation, the only definite result which emerges is that the intensity is much greater in the vertical direction than in any other. Very recently Mr Medicus has published<sup>2</sup> the results of observations made by a method similar to mine described below. But the number of coincidences registered in the different directions is perhaps insufficient for a definite deduction. There is therefore a great need for a trustworthy series of measurements, made with an apparatus having sufficient resolving power to allow the true distribution to be deduced. An exact knowledge of this distribution is of no little importance. In the first place, it is a necessary element in the exact discussion of many other experiments. Secondly, it is interesting to see whether the observed zenithal distribution can be due to the absorption by the atmosphere of a radiation which was originally isotropic.

With these considerations in view, I have attempted a thorough investigation of the problem. I wish to express my sincere thanks to Prof B Rossi for suggesting this problem and for his advice and help.

The measurements were made in a wooden hut, the walls and roof of which were 3.5 cm thick, especially built for the purpose on a terrace of the Physical Laboratory of Arcetri, which is so located that its

horizon is unobstructed, except partially towards the east by the hill of Arcetri.

For the purpose of observing only the rays coming from a relatively small solid angle, I used the coincidence method between the impulses of two Geiger-Müller tube counters. These had a diameter of 3 cm and an effective length of 20 cm. The coincidences were registered by Rossi's method.<sup>3</sup> The axes of the two counters were placed horizontally at a distance of 18 cm apart.

The two tube counters were mounted so that the plane containing the axes of the two tubes could be rotated round a horizontal axis (the latter being exactly in the north and south direction), so as to make a varying inclination with the vertical. The observations were made with the inclination towards the west.

To eliminate the softer component of the penetrating radiation, a block of lead 5 cm thick was interposed between the two counters at a distance of 0.7 cm from the lower one. This precaution seemed advisable both because this softer radiation may very probably be partly of secondary origin and because the walls of the hut are likely to have an influence only on this softer radiation. The results are as follows:

|                                    |   |            |            |            |            |            |
|------------------------------------|---|------------|------------|------------|------------|------------|
| $\phi$                             | = | 0          | 20         | 40         | 60         | 75         |
| Coincidence                        | = | 1616       | 1441       | 1018       | 404        | 181        |
| in 17 <sup>h</sup> 20 <sup>m</sup> | = | 93.2 ± 2.5 | 83.2 ± 2.5 | 58.4 ± 2.2 | 23.3 ± 1.7 | 10.5 ± 1.4 |
| No. per hour                       | = |            |            |            |            |            |

In the first line are shown the values of the angle  $\phi$  between the vertical and the plane containing the axes of the counters, in the second the total number of coincidences observed in 17<sup>h</sup> 20<sup>m</sup> in each of these positions. The casual coincidences, amounting to 13.8 per hour, have been deducted from the above figures. Lastly, the third line shows the mean value of the number of coincidences in an hour, with the corresponding statistical error. These latter values are represented graphically in Fig 1.

FIG 1

Without entering into a full discussion of these results, which will be described in detail shortly, I note that the intensity curve, as a function of the zenithal angle, seems to be somewhat sharper than would be expected from absorption by the atmosphere.

Finally, I wish to express my thanks to Mr L. Emo for the friendly help given me during part of these investigations, and to the Consiglio Nazionale

delle Ricerche, which has supplied the funds necessary to carry out a group of researches on the penetrating radiation

### Geophysical Prospecting

MAY I, as one of the editors of "The Principles and Practice of Geophysical Prospecting" (Cambridge University Press, 1931), ask NATURE to publish the following correction? It is made at the request of Mr E H Booth, one of the contributors to the chapter on seismic methods, and it has the approval of Sir Edgeworth David

An error has crept into the discussion of field tests at Tallong, N S Wales, given on p 229 In Fig 176 the east and west indicators have been accidentally interchanged The same figure indicating the interpretation placed on the geophysical work shows the existence of a mass of alluvium over a mile wide and upwards of 200 feet deep In the geological map of the Tallong area, reproduced on p 228, no such deposit of anything approaching to this extent and thickness is shown, though the omission of a geologist to indicate such a mass of material would be very serious As a matter of fact, the deposit is mostly decomposed granite in situ The mistake in representing this as alluvium is obviously due to the fact that decomposed granite transmits seismic waves comparatively slowly, as would alluvium, namely, at the rate of about 3000 feet per second Actually there is outcropping granite over this portion of the area, as shown in the geological map The use of the term 'alluvial velocities' as a general expression for the velocity of a wave through incoherent material is apt to be misleading, and might be discontinued

In fairness to the geologists who surveyed this area years ago, it must be admitted that the geophysical interpretation, while accurately classifying the material according to the velocities of the transmitted waves, was inaccurate in its presentation of the geological structures of the Tallong area. It is regretted that through an oversight no reference was made to the fact that the geological map of Tallong, reproduced in Fig 175, is almost entirely the work of Dr W G Woolnough, geological adviser to the Commonwealth Government of Australia The accuracy of this map has been amply verified by later observers

### Automatic Recording of Heaviside Layer Heights

EXPERIMENTS made to determine the effective height of the Heaviside layer have shown extremely varied results, and it has been clear that, in order to obtain any idea of the normal state of the upper atmospheric ionisation, it is unsatisfactory to take observations at widely spaced intervals of time Continuous automatic records of effective height are required

Gilliland and Kenrick have recently published a preliminary account of a method of obtaining such records<sup>1</sup> I have independently developed a method which differs in several important respects from that of Gilliland and Kenrick The 'echo' method of

Breit and Tuve is used A transmitter is caused to emit short 'pulse' signals with a constant interval by being driven from the A C mains The signals, together with any echoes, are then arranged to give a stationary pattern on a cathode ray oscillograph screen at the receiver<sup>2</sup> The tips of the peaks representing the signal and echoes are photographed on a film moving at about three inches per hour

FIG 1—Specimen records of height of Heaviside layer

The sample records shown in Fig 1 have been obtained in this way, and show the following results

- (a) Jump from E layer (110 km) to F layer (330 km)
- (b) Splitting of echo from F layer The upper component apparently vanishes due to electron limitation, while the lower component persists

It is hoped to publish further details of the method in the near future

### Photo-Conductivity of Diamonds

SINCE reporting that we had found a diamond transparent at  $8\mu$  in the infra-red and so far as  $\lambda 2300$  in the ultra-violet region of the spectrum,<sup>1</sup> whereas most diamonds have an intense infra-red absorption band at  $8\mu$  and no longer transmit beyond  $\lambda 3000$ , we have come across four more diamonds of that type transparent in both regions Some of these diamonds respond to radiation in a manner which is striking and, we believe, hitherto unrecorded

Gudden and Pohl,<sup>2</sup> and also Miss Levi,<sup>3</sup> succeeded in obtaining a current when certain diamonds were illuminated with ultra-violet light from a mercury arc, provided at the same time a considerable voltage were applied to surfaces of the diamond

This we can repeat with all the diamonds of the transparent character, but most of them on illumination without the application of any voltage produce a current In one case this is as much as is equivalent to a galvanometer throw of  $1 \times 10^{-7}$  ampere, while a back E M F of about 0.6 volt is required to bring the galvanometer back to zero This effect was obtained with contacts of brass, lead, or graphite

Exploration of the activating region by means of the large monochromator of King's College, London (kindly put at our disposal by Prof Allmand), showed that the most effective wave-length for photo-conductivity in the transparent diamonds is about  $\lambda 2300$

### The Hydrogen Chromosphere

THE slow decrease of the density of hydrogen with increasing height in the solar atmosphere requires a consideration of the force opposing gravity. As is well known, radiation pressure is insufficient for this purpose, at least if the radiation-intensity is not wholly different from the value derived by extrapolation from the solar spectrum in the visible region.

However, the existence of an outward moving stream of  $\text{Ca}^+$  atoms requires the investigation of the acceleration imparted to the H-atoms. This acceleration depends on the density  $\rho$  of the  $\text{Ca}^+$  atoms and their systematic outward velocity  $v$ . The value of the required product  $\rho v$  may be deduced from the contour-asymmetry of the K-line, as measured by Minnaert. I have derived the value<sup>1</sup>

$$\rho v = 0.8 \times 10^{-12},$$

however, owing to the circumstances of the problem, this value has a large degree of uncertainty and requires revision in the future.

Combining the determination of  $\rho v$  with a classical computation<sup>2</sup> of the effect of the collisions on the hydrogen atoms, I have deduced the ratio of the acceleration imparted to a hydrogen ion at rest to the acceleration of gravity. The resulting value of this ratio is 1.1. The value for a hydrogen atom would be much smaller on account of the shielding effected by the bound electron.

Though inconclusive at present on account of uncertainties in the values involved, this computation induces me to adopt as a working hypothesis the convection of the hydrogen atoms by the outward moving  $\text{Ca}^+$  atoms.

The fact that the motive force of the  $\text{Ca}^+$  ions only is present at comparatively great heights in the solar atmosphere concentrates its action especially on hydrogen.

A more detailed analysis of the motion of hydrogen will be published elsewhere. J. WOLTJER, JR.

### Polarisation of Raman Scattering

THE use of an improved technique has enabled us to obtain more precise measurements than formerly of the polarisation of the lines in Raman spectra. A systematic study has now been made with many liquids. An important result obtained is that no line has a depolarisation greater than 6/7, and that earlier reports by various workers indicating a larger depolarisation in certain cases are not correct. The limiting value of 6/7 is obtained in many instances, especially in all cases of a rotational scattering, whether by gases or by liquids. Many vibration lines also exhibit this high degree of depolarisation, as, for example, the frequencies 605, 1584, and 1605 of benzene, the two bands at 189 and 1398 in formic acid, the line at 750 in thiophene, the frequencies 106, 131, and 403 in tin tetrachloride, and the corresponding lines given by the tetrachlorides of carbon, silicon, and titanium. In all these cases, the explanation suggested in the last paragraph of Bhagavantam's note in *NATURE* of Jan. 30, 1932 (p. 167), is evidently applicable.

A careful determination has been made with the intense 992 line of benzene and it is found that it exhibits a genuine depolarisation of 7 per cent. The tetrachlorides of carbon, silicon, titanium, and tin exhibit an interesting progression in the behaviour of their strongest lines: the lines 459, 426, 382, and 367 given respectively by these compounds exhibiting

depolarisations of 4, 11, 12, and 16 per cent. That these lines, which correspond to a symmetric oscillation of the tetrahedral molecules, exhibit a genuine depolarisation is not surprising in view of the well-attested optical anisotropy of these molecules. It is found that the Rayleigh scattering by all the tetrachlorides is accompanied by a rotational Raman scattering and is depolarised to an appreciable extent, which increases with increasing atomic number of the central atom.

### Constitution of the Keratin Molecule

IN a note which appeared recently in these columns, Speakman and Hirst<sup>1</sup> recorded comparisons of the work necessary to stretch wool fibres in water, in acids, and after treatment with nitrous acid. The conclusion they reached was that acids disrupt a linkage of the type  $\text{R}_1 - \text{COO} - \text{NH}_2 - \text{R}_2$  in the keratin molecule formed from acidic and basic units in adjacent polypeptide chains. Taking the figures quoted by Marston<sup>2</sup> for the amino-acid composition of wool, it was shown that the dibasic aspartic and glutamic acids were collectively present in quantity roughly proportional to that required on the assumption that they entered into a linkage of the type postulated with the  $\epsilon$ -amino group of lysine and the guanidine group of arginine.

The suggestion put forward by Speakman and Hirst is worthy of consideration in explaining the properties of wool fibres, although they have neglected in their calculations one factor which makes the agreement or correspondence between the quantities not so close as would appear from their figures. They have assumed that every molecule of glutamic or aspartic acid has one carboxyl group free to enter into salt formation with an amino group. Wool yields upon hydrolysis 1.2 per cent of 'ammonia'- or 'amide'-nitrogen. Now, the general opinion among protein chemists is that this ammonia exists in the protein in the form of acid-amide linkages with one or other of the dibasic amino acids<sup>3, 4, 5</sup>.

Osborne<sup>6</sup> was one of the first to point out the parallelism between the yields of ammonia and of dicarboxylic acids from various proteins, and although hydroxyglutamic acid was only discovered afterwards,<sup>7</sup> it will be recalled that Luck<sup>8</sup> succeeded in isolating a complex from caseinogen, representing at least one-third of its ammonia nitrogen, in which a peptide of lysine-glutamic acid amide was the principal constituent. Alternative theories as to the origin of ammonia nitrogen, for example, ureide linkages,<sup>9</sup> which have at one time or another been proposed, have all had eventually to be abandoned.

Speakman and Hirst must therefore deduct 12.6 per cent by weight of glutamic acid from the 12.9 per cent contained in wool, since this is presumably in combination with the 1.2 per cent of ammonia nitrogen, leaving 0.3 per cent of glutamic acid and 2.3 per cent of aspartic acid (say 2.6 per cent in all) free to enter into the type of union they postulate with the basic amino acids. As they state, "Using Marston's data, the arginine and lysine are together equivalent to an amount of glutamic acid equal to 11.4 per cent by weight of the wool." Even if the more recent figures of Vickery and Block,<sup>10</sup> independently confirmed by Stewart and me,<sup>11</sup> of 8.6 per cent arginine instead of 10.2 per cent and 2.3 per cent lysine instead of 2.8 per cent, be taken, these bases, for complete combination, would require 9.57 per cent of glutamic acid—nearly four times the amount actually available.

So far, no systematic search has been made for

hydroxyglutamic acid or for hydroxylysine in wool, and the above considerations are naturally confined to existing data

A second point in the communication under consideration raises the question whether hydroxylysine may not be a constituent of wool. Speakman and Hirst found 0.94-1.11 per cent of amino nitrogen in the wool they examined, the  $\epsilon$ -amino groups of 2.8 per cent lysine would account, however, for only 0.27 per cent. They included 0.82 per cent as being derived from 10.2 per cent of arginine, making 1.09 per cent in all, in agreement with their experimental findings. The guanidine group of arginine does *not*, however, yield nitrogen with nitrous acid under the usual conditions.

Van Slyke and Birchard<sup>12</sup> have shown that in most proteins the free amino nitrogen corresponds very closely to one-half of the lysine nitrogen, and in the present case it may be concluded that wool probably contains hydroxylysine or other diamino acid in addition to lysine.

Our uncertainty as to the composition of the keratin molecule (only one complete analysis is upon record, that of Abderhalden and Voitnovici<sup>13</sup> in 1907) makes it imperative that trustworthy quantitative chemical evidence should be available to test the newer physical theories of keratin structure now being advanced.

### Preparation of Anhydrous Chlorides and Metallic Couples

DURING investigations involving the Grignard reagent it was noticed that, when the magnesium was in contact with lead chloride under ether, bubbles of gas were evolved, which were found to arise from traces of water in the ether.

This led to the investigation of the action of water on a metallic salt (chloride, sulphate, nitrate, etc.) when mixed with a metal lower in the electropotential series than the metal of the salt.

It was found, especially in the case of the chloride, that reaction in many cases occurred with explosive violence, the more electro-positive metal replacing the less electro-positive metal of the salt. Typical cases of such violent reactions were given by zinc and aluminium respectively when in contact with (a)  $\text{HgCl}_2$ , (b)  $\text{PbCl}_2$ , (c)  $\text{Cu}_2\text{Cl}_2$ , etc. Such mixtures are very effective for detecting the presence of traces of water in organic liquids.

These observations led to heating the mixtures to ascertain whether in cases of volatile chlorides a simple method of preparation were possible, and it was found that when excess of aluminium was heated with lead chloride a quantitative yield of aluminium chloride was obtained. When excess of aluminium is not taken, a yellow crystalline substance (probably a double chloride of lead and aluminium) is formed along with the aluminium chloride. The reaction takes place very readily and can be carried out in a

soft glass test-tube. Aluminium and cuprous chloride, also aluminium and silver chloride, react easily to give aluminium chloride. For syntheses by the Friedel Crafts' reaction, the aluminium chloride can be quantitatively distilled over by connecting the test-tube with a bent metal tube to the reaction vessel. Instead, the mixture may be placed in the reaction vessel itself and gently warmed, the aluminium chloride condenses on the side of the flask, and the metallic residue can be shaken out of the vessel. The chloride is then washed down the side of the vessel with the organic solvent, or dislodged by means of a glass rod.

Zinc and stannic chlorides are readily prepared by the action of (a) zinc on cuprous chloride, (b) tin on cupric oxychloride. The cupric oxychloride is prepared by fusing ordinary hydrated cupric chloride on a tray, the fused mass being ground up in a mortar and transferred to a distillation flask. Powdered tin is dropped into the flask, the neck being closed by a cork wrapped in tin-foil. On gently heating, anhydrous stannic chloride distils over and is collected in a test-tube placed on the side arm. In this way anhydrous stannic chloride in excellent yield can be very quickly prepared.

Zinc and cuprous chloride when left on a filter paper react, causing the paper to ignite. When magnesium and cuprous chloride were heated together an explosion occurred, the flask was shattered and coated with copper.
